P.S.—I regret to see that a mistake has been made in the number of jacks required for exchanges of 2,000 and 2,400 subscribers. They should, of course, be—as I think I wrote them—14,000 and 19,200, not 1,400 and 1,920 as printed.

STEAM TURBO GENERATING PLANT.

SIR,—My attention has been called to a letter in your last issue from the well-known engine builders, Messrs. Belliss and Morcom, Limited, in which figures given in my paper recently read before the Leeds Section of the Institution of Electrical Engineers are adversely criticised. In the case of the Electric Construction-Belliss set in the Leeds electricity works, I gave the steam consumption per kilowatt-hour at 19 9lb. (the figure given to me as approximately accurate by the city electrical engineer), whereas Messrs. Belliss put it at 19·49lb., including boiler and steam-pipe losses, which correction I accept.

Although no definite statement is actually made, yet the whole letter is cleverly drawn out to convey the impression that reciprocating engine plants are as economical as turbine plants, and complaint is made that I compare the efficiency of reciprocating engines and turbines of about equal sizes, but working under different conditions, especially with regard to superheat and vacuum.

My reply is that it is quite fair to make comparisons between the plants mentioned in my paper, because the steam consumptions given are those obtained *under actual daily working conditions.* To the plea that a particular reciprocating plant would give a better efficiency with greater superheat and better vacuum, my reply is, Why do you not then provide the greater superheat and better vacuum, and thus obtain the alleged greater economy? Are we to assume that the engineers who have these plants under their charge, or that the engineers who built them and put them down, disregard their own fame and the interests of their employers so much that they are content to waste coal and boiler power rather than improve their vacuums and raise the temperature of superheat?

Engineers who have had an extended experience with both reciprocating steam-engines and steam-turbines know full well that to raise the superheat over, say, 60deg F., at the stop valve, means with the reciprocating engine: (1) increase in the difficulties and risks of running; (2) increased wear and tear and heavy bills for upkeep and repair; (3) an expensive oil, and much of it, for cylinder lubrication.

In the steam-turbine none of these difficulties and expenses present themselves, hence we see in actual every-day work reciprocating engines working with little or no superheat and turbines working on high superheats.

Messrs. Belliss state that with 237deg. F. superheat they can reduce the steam consumption in their Leeds plant from 19·49lb. to under 16lb. per kilowatt. Then why is not this desirable and valuable economy effected? I trow it is because both Messrs. Belliss know and the city engineers know that with such high superheat all the difficulties named above would then be at once encountered, and the

Digitized by Google

extra expenses and risks thus brought about would more than counterbalance the temporary economy to be gained.

Thus, my contention that my comparisons are fair because they are on practical lines is a sound contention, and it applies with equal force to the comparisons drawn between the steam-turbine and the Sulzer-Kolben plants named in my paper.

Again, as regards vacuums, engineers with both classes of plant know that by reason of gland and packing leakage it is more difficult to maintain high vacuums with reciprocating engines than with turbines.

Doubtless Messrs. Belliss would like to prove that reciprocating plants are more economical than steam-turbines, but the weight of evidence is against them; it is not to be expected, however, that engine builders will allow the present rapid development of the steam-turbine to proceed without making some efforts to stem the tide, futile though it may be.

I repudiate Messrs. Belliss's insinuations that I am interested in booming the turbine, or that my paper contains "misleading statements"; the figures given are to the best of my knowledge correct, and, moreover, they are not theoretical values, as is the figure of improved economy given for the Leeds plant, but the outcome of everyday practice, which alone is the true standard upon which to found our conclusions.

With reference to the postcript, I would correct it and put it thuswise: It should always be borne in mind that the cost of obtaining the high vacuum necessary for efficiency with *either reciprocating engines or* steam-turbines may become a very formidable item in the majority of inland stations.—Yours, etc., GEO. WILKINSON.

THE GROUPING OF CELLS.

SIR,—Some months ago you allowed me to point out the inaccuracy of the usual rule for grouping cells for maximum current, and to put forward a better rule. I should now like to give a simplified statement of my rule, with a slight improvement upon it.

According to the usual rule, the cells must be arranged in a *simple* group—that is to say, a group consisting of a number of equal *ranks*, each rank consisting of a number of cells connected in parallel, and the ranks being connected together in series. Fig. 1 shows a group consisting of four equal ranks, each rank consisting of three cells, and Fig. 2 shows the same number of cells arranged in three ranks of four instead of in four ranks of three. They might also be arranged in six ranks of two, in 12 ranks of one, or in one rank of 12, and the rule says that the grouping which will give the maximum current is the one whose resistance approximates most closely to the resistance of the external circuit. But I find that a considerably greater current than is obtainable with this rule can frequently be obtained from a *compound* group—that is to say, a group consisting of two

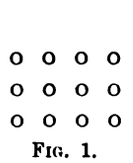

FIG. 1.

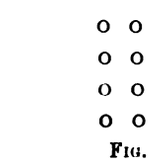

FIG. 2.

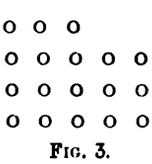

FIG. 3.

simple groups connected together in series, the ranks in one of these groups each containing one cell more than those in the other, as in Fig. 3, which consists of three ranks of four connected in series with two ranks of three. The number of ranks into which the available cells are to be divided is generally the nearest whole number to K in the following formula:

$$K = \sqrt{\frac{C \times X}{R}},$$

where C is the number of cells, X the external resistance, and R the resistance of each cell. This formula may lead to a simple grouping, in which case that is the best possible one that can be adopted. But if it leads to a compound grouping in which the larger ranks are more numerous than the smaller, they should, as far as possible, be made still more numerous at the expense of the smaller ranks. The grouping in Fig. 4, for example, should be changed to that in Fig. 5.

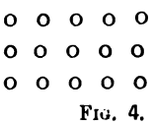

FIG. 4.

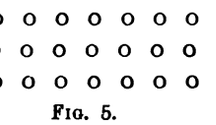

FIG. 5.

And if the formula leads to a grouping in which the smaller ranks are more numerous than the larger, they should be, as far as possible, made still more numerous at the expense of the larger ranks. The grouping in Fig. 6, for example, should be changed to that in Fig. 7.

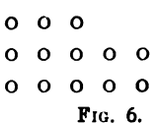

FIG. 6.

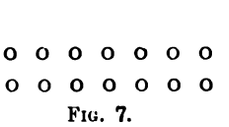

FIG. 7.

Two examples—one with a very small number of cells and one with a large number—will suffice to show how the above rule is applied, and to demonstrate the serious inaccuracy of the usual rule.

Suppose we have three one-volt and one-ohm cells and an external resistance of 1½ ohms. The formula

$$K = \sqrt{\frac{3 \times 1\frac{1}{2}}{1}}$$

gives 2 as the nearest whole number, and shows that the cells should be arranged in a compound group consisting of one rank of one and one rank of two, the resistance of which would evidently be 1½ ohms. The total resistance, external and internal, would, therefore, be three ohms, and dividing this into the number of volts, which is evidently two, we find that the current obtained would be 0·667 ampere. But the usual rule would say that the cells should be arranged all in parallel (in one rank of three), and the current obtained by this arrangement would be only 0 545 ampere.

Now suppose we have 101 such cells and an external resistance of 2½ ohms. Our formula gives

$$K = \sqrt{\frac{101 \times 2{\cdot}5}{1}},$$

the nearest whole number to which is 16, and we therefore arrange our cells in a compound group, consisting of 11 ranks of six and five ranks of seven (we leave the grouping like this, as it is impossible to increase the ranks of six at the expense of the less numerous ranks of seven). The current obtained from this arrangement would be 3·17 amperes. But according to the usual rule the cells should be arranged all in parallel, giving a current of only 0·4 ampere, about one-eighth of that obtained with the rule explained above.—Yours, etc., W. F. DUNTON.

CALCUTTA TRAMWAYS.

SIR,—With reference to your note *re* Calcutta tramways on p. 494 of your issue for Oct. 2, 1903, I should like to say that the comments of the local paper you quote are absolutely unreliable and steeped in prejudice, owing to causes well known in this city. In point of fact, I believe that the tramway company has not been to blame for a single fatal accident since the conversion, and for very few of the minor accidents, such as collisions, which inevitably occur on a new system. It must be remembered that not one driver had ever previously seen a car other than a steam or horse car, that they have capacity to pick up very little technical knowledge, and that they have to drive through narrow streets seething with coolies used to nothing but bullock carts. This being so, I consider, as a constant traveller on the system, that the running is most praiseworthy.

I may add that your contemporary bases its opposition often on no evidence, or on cases in which the company have been specifically absolved from blame; especially on one where a young man tried to jump off a moving car and fell underneath it. In the latter case another enlightened paper suggested that the company should pension his relatives.—Yours, etc., J. W. M.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

635. Describe some method of extracting air from water to be used for condensing purposes, the water having been raised from a bore-hole by compressed air.—BUBBLE.

636. Give sketches of how you would arrange to control a pump and motor of 2 h.p., 550 volts, two miles away to indicate when the water was at maximum and minimum height.—G. H.

ANSWERS.

Question No. 627.—What are the advantages and disadvantages of the underfed type of mechanical stoker, as compared with the moving grate and shifting firebar types?

Best Answer to No. 627 (*awarded* 10*s.*).—There are two types of underfed stokers in general use, the one feeding the coal intermittently by means of a ram or plunger, and the other having a continuous screw feed. They are, however, alike in principle, and most advantages of the one will apply equally to the other, so we will discuss them in turn.

The former, largely used in America and to a more limited extent in this country, consists essentially of a U-shaped tapering trough, extending the length of the grate, into the forward end of which the coal is fed through the usual hopper. The feed motion is given by a ram, which is worked at intervals by a piston in a steam cylinder fixed to the body of the stoker. The coal is thus pushed along the trough, the tapering form of which, in combination with a rod attachment in the trough which is worked with the ram, causes coal to rise to the surface, where it is first coked and then burnt entirely, the fire always being on the upper surface of the coal. The distilled gases have all to pass directly through the incandescent mass of the fire, and the combustible portion is thus consumed. The necessary air is supplied from a blower through tuyere blocks at the edge of the trough, and has also to perform the work of spreading the coal over the area of grate not occupied by the trough. The arrangement for working the steam distribution valve at required intervals is very simple and effective, consisting of a hollow rocking tube with a hollow vessel at either end, partly filled with water, which flows from the upper vessel to the lower, and when lower is full, tips a counterweight which opens steam-valve to cylinder. The resulting motion of the piston and ram restores the vessels to their original position. The speed of flow of the water is regulated by a valve in the tube.

The advantages claimed for this stoker are as follows: (1) Great simplicity, very few moving parts, and none of these in contact with the fires. (2) Consequent durability and absence of repairs. It is said that many of these stokers have been in constant use for five years without costing anything for repairs. (3) Economical working at all loads. (4) Smoke prevention even when forcing fires. (5) Cheap fuels smokelessly burnt, thus reducing coal bills. (6) Complete burning of all combustible, there being no bars for small coal to drop through. (7) Positive control of air supply. (8) Less air used than with any other method of firing, as the air is introduced only where it is needed, below the fire, and the amount is regulated by the blower supplying it. It is claimed that hardly any more air is used than is theoretically necessary for complete combustion, whereas other methods use from 50 to 100 per cent. more. This ensures better utilisation of the heat, for the gases are less diluted with surplus air, and so leave furnace in less volume and at higher temperatures; therefore the velocity is less, and the slower rate of travel results in a better transference of heat to the boiler. The gases are said to leave the boiler at lower temperatures than is usually the case with other stokers. (9) Forced draught being used, no high stack is needed. (10) Simplicity of erection, the work of which can be done by any ordinary mechanic. (11) No shafting or engine required, each stoker being self-contained. (12) No firebars, but simple dead plates. (13) No steam jets. (14) Hopper being below fire level, the labour of lifting the coal is much less than when it is high up. (15) Increase of boiler capacity.

Against these advantages must be balanced the following disadvantages: (1) The stoker not being self-clinkering, periodical cleaning out is necessary, with its attendant inconveniences of turning down fires, thus stopping the steaming of the boiler, and opening of firedoors, admitting cold air. Moreover, as it has been found in practice that a very heavy fire gives best results, as much as 18in. being used for most bituminous coals, the time of turning down is much prolonged. In an electricity supply station, where the maintenance of the steam pressure at critical times is everything, and the loss for half an hour of a single boiler might be the cause of the stoppage of supply to certain districts or even the whole town, this might well prove a serious objection. It must however, in fairness, be stated that it has been found possible to delay the time of cleaning out longer than would be possible with hand-fired boilers. (2) The air blast being relied on to spread the coal to make up the portion of the fire outside the trough, has to be of greater pressure than that in general use for this class of work, and thus will require more power. (3) It has been found that by far the greater portion of the heat is concentrated at the trough, and this has been found a great source of trouble, many burnt-out tubes in water-tube boilers having been attributed to this. To obviate this the stoker has been set as much as 6ft. below bottom row of tubes. (4) The necessity of cleaning out the fires involves extra labour over other types of stokers.

Reviewing the above advantages, Nos. (4) (5) (8) (15) are shared in a greater or less degree by other stokers, and the others only need be considered. Nos. (1) and (2) should make the cost compare favourably with other types. No. (9) is only an advantage in a new installation, as in the case of an extension the high stack will probably be already existing. Of the disadvantages, Nos. (1) and (3) are of great importance, (3) practically meaning a reduction of grate area, and, therefore, an increased fuel consumption per unit area, with the attendant dangers of burnt-out tubes, etc. It may be mentioned that an automatic device has recently been introduced in America for regulating the supply of coal and the draught to suit the varying loads.

The other type of underfeed stoker has very similar characteristics, but the feed is by a continually revolving helix in the trough, and the grate is of an inverted V-shape with the sides composed of a series of tuyere blocks, between which air is admitted. The coal as it rises from the trough slides down these sides, and a much better distribution of fire is obtained than in the other type. The other disadvantages still remain, and the cleaning out is said to be even more awkward. Also the continuous feed has been found undesirable owing to its breaking up the fire. As each is self-contained and the movement is continuous, it practically means having a separate engine for each stoker, which must be wasteful of steam.

In conclusion, it would seem that the latter type is preferable, on account of the better distributed fire; that either is admirably adapted for smokelessly and economically burning low-grade fuels, and that the cost of repairs to stokers would be low, but that the necessity for frequent clearing out and the heavier repairs bill to boilers in the first type would tell strongly against it in the minds of many. It certainly has not so far found much favour with central-station engineers in this country.—R. S. B.

Answer to No. 627 (*awarded* 7*s.* 6*d.*).—Mechanical methods of stoking have not made nearly the progress in this country as in America, and probably the principal reason for this is that while in the States the greater proportion of boilers are of the externally-fired type, the internally-fired

Digitized by Google

boiler is generally preferred here. Externally-fired boilers lend themselves very readily, indeed, to the adaptation of almost any system of mechanical stoking, there being plenty of room to fix the gear, whilst the available space on an internally-fired class is necessarily limited. As a natural result, therefore, of the ease of application, the mechanical stoker has been considerably more developed in America than in this country, and more especially has this been so in the case of the underfeed class of mechanical stoker. Although in recent years there has been considerable progress made in the application of mechanical stoking apparatus with us, the advancement has been almost exclusively in the direction of the overfeed system, the use of underfeed stokers being extremely limited.

Before discussing in detail the various advantages claimed for the two systems, it is, perhaps, necessary to briefly consider their essential points. The overfeed system is, in its simplest form, merely an adaptation of the ordinary hand-fired furnace, fuel being admitted through the front of the furnace on to the top of the fire. The stokers operating upon this system may be divided into two classes—(*a*) the sprinkler or shutter type, and (*b*) the coking class, which are again sub-divided into (1) the ram or plunger, with moving bars; and (2) the chain-grate type. These various types having already been somewhat exhaustively discussed in these columns, it will therefore only be necessary to briefly refer to their operation.

Sprinkler Type.—This stoker consists of a shutter or flapper operated by means of suitably arranged springs; the shutter being sharply released, knocks the coal from a shaped plate in front of the furnace. The coal falls upon the plate from a hopper above, the supply being regulated to suit requirements. By a simple adjustment of the springs, the power of the shutter is so varied that the coal falls upon any part of the fire as required.

Coking Stoker—Ram Type.—As its name implies, this class of stoker consists essentially of a ram or rams which push the coal in at the front of the furnace on to a coking plate, from where it is gradually worked to the back by means of suitably arranged moving firebars.

Chain-Grate Type.—Although considerably different in their construction, practically the same end is obtained with the chain grate as with the ram type. With the chain grate the rams and moving firebars are dispensed with, and a series of endless chains are provided. These chains are arranged side by side, and revolve over two drums, one at each end, the coal entering at the front and being gradually carried to the back, where the unconsumed portion drops into the ashpit.

Underfeed System.—The principle of underfeed stoking consists essentially of feeding the fuel slowly, and for full economy continuously, through the underneath of the fire-grate, the coal, as it gradually reaches the top and hottest part of the fire, being slowly roasted and coked, the coal being released and immediately ignited by the air, which is supplied through specially constructed ducts in the stoker grate, and the coal, therefore, reaches the top of the fire practically as coke. Underfeed stokers may be divided into two classes: (A) the continuous-feed type, and (B) those equipped with plungers or pistons. The continuous-feed stoker, Class A, consists in the "American stoker" of a screw conveyor, which commences at the hopper and extends the full length of the furnace in what is termed the conveyor pipe. The conveyor is so arranged that the coal is distributed equally over the entire surface. Air is supplied through a pipe just under the hopper, the pipe communicating with what is termed the wind box. This wind box opens into the magazine, the upper edge of which is arranged with tuyeres or air ducts, through which the air is discharged to the fire. The driving arrangements are very simple, consisting of a small steam motor with a simple reciprocating piston, which actuates a pawl and ratchet wheel, the wheel being attached direct to the conveyor shaft. In the intermittent-feed stoker, Class B, the grate and system of admitting air is on the same principle as Class A, but the coal is forced up through the fire by means of plunger or piston instead of the spiral conveyor. This latter type has not been nearly so widely adopted as the continuous-feed type. It is apparent that a constant feed must be superior to an intermittent supply, as the latter has two rather serious objections: (1) there is a tendency during the intervals between feeding for coke to form in places, and through which the air cannot readily be forced, so that it takes a course through the fire where thinnest, thus causing blowholes; (2) when the piston enters these masses of coke are broken up suddenly, with the result that a considerable amount of smoke may be formed. In the following comparison therefore between the over and under feed systems of stoking, it will be understood that the continuous feed class is being considered.

In order to make the comparison as clear and concise as possible, we will consider the relative advantages and disadvantages under several headings, including economy, smoke prevention, cost, etc.

Economy.—It is generally conceded that the coking type of stoker is more economical than the sprinkler, but the actual economy resulting from mechanical stoking depends upon so many things differing considerably in almost every individual case, that although most elaborate tests have from time to time been made, it is almost impossible to make a really reliable comparison. The underfeed type of stoker may be taken as at least as good in this respect as the coker stoker, and possibly slightly better results may be expected.

Smoke Prevention.—The underfeed stoker is probably the best practical smoke preventer in everyday use. The continuous feeding of green coal on the underside of the grate, from where it gradually works to top of the fire, by which time it is practically coke, ensures almost complete combustion, and the only way in which smoke can be produced is when, as sometimes happens, the green coal forces its way through the fire without going through the coking process. The greatest offender as regards smoke is the sprinkler, which produces an almost continuous stream of smoke, which, however, is of a very light colour and scarcely noticeable.

Cost.—The first cost of either of the other types of stokers is considerably more than the sprinkler, this type also costing least for maintenance. The underfeed stoker is very expensive in first cost, and also, owing to its specially-constructed furnace plates, rather expensive to maintain, but this item depends to a great extent upon the arrangements and conditions of working rather than upon the type of stoker itself.

Forcing.—One of the great objections to all systems of mechanical stoking is the inability to force the boiler evaporation in case of emergency. It is impossible to force the underfeed stoker, and the coking stokers also cannot be forced to any appreciable extent. The rate of evaporation may be increased with a sprinkler stoker, but, of course, at the expense of economy and the production of smoke.

Accessibility for Repairs.—The chain-grate stoker is most readily examined, as it can be bodily removed from the boiler. The underfeed stoker is more difficult of access than either moving types.

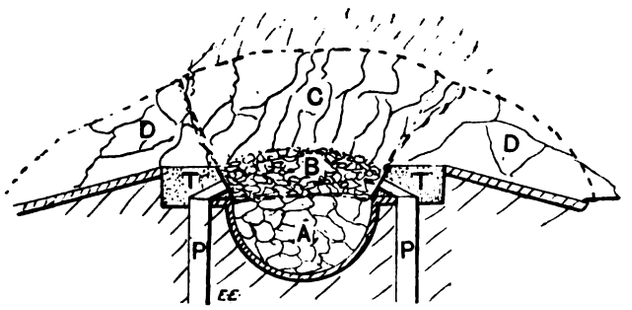
Draught.—The underfeed stoker cannot be worked without some system of forced draught, and in certain cases this may be rather a serious objection.

In conclusion, it may be stated that the sprinkler stoker, in this country at least, is rapidly gaining favour for applying to Lancashire and similar boilers, while the chain-grate type is most extensively applied to water-tube boilers. The underfeed stoker is still somewhat a novelty here, and, notwithstanding several distinctive merits, will not apparently come into extended use.—F. A.

Answer to No. 627 (*awarded* 5*s.*).—The chief advantage of the type of mechanical stoker in which the fuel is fed into the fire from a trough beneath, is that more complete combustion is possible without an excessive supply of air than with the other types of stokers. The accompanying sketch, which shows a section through the furnace, will give an idea of its action. The unburnt fuel is introduced into the trough, A, it is slowly raised by the action of the ram till it is moved into the space B, where it meets with the draught of air which is forced by a fan up the passages, P P, through the tuyere blocks, T T, into the furnaces. Here the fuel is ignited, and the hydro-carbons contained in it burnt away; it is then raised into the space C, where

Digitized by Google

the process of combustion continues until all the fixed carbon is consumed; the residue in the form of clinker and ashes is pushed by the slow upward motion of the mass on to one side in the space D, where it remains until removed. The gases generated in the space B have to pass through the white-hot fuel in C before leaving, and so become completely burnt, thus ensuring smokeless combustion even of bituminous slack.



The advantage of this method of feeding is especially evident when used in connection with those types of water-tube boilers in which the gases rise vertically from the grate and strike on to cold water tubes; in other stokers the gases have not space to mix properly, and thus form dense volumes of smoke, but in this type the gases mix before reaching the surface of the fuel. Another advantage of the underfeed stokers is that they do not need the use of moving parts in the fire, all the mechanism being quite outside the furnace—this reduces the maintenance costs.

The chief disadvantage is that the draught cannot be produced by a chimney owing to the large pressure needed (from two to four inches of water), this necessitating the use of a fan, but the cost of this is usually made up by the cheapness of the stoker itself and the possibility of burning the cheapest coals.—E. J.

Answer to No. 627 (*awarded* 5*s.*).—The advantages of using the underfeed type of stoker are as follows: In this stoker the air to the furnace is supplied by a volume blower, and is delivered in the approximate proportion of 150 cubic feet of air per pound of coal fed, and at a pressure ranging from ½oz. to 1oz. at the tuyeres. This pressure is only such as to admit of the thorough mixing of the air with the coal, and is in no sense of the word a blast. The advantage of this arrangement is that, being independent of natural draught and the supply of air and coal under complete control, the fire can be forced at a moment's notice, and can be as quickly reduced. Further, the fuel is thoroughly coked before reaching the zone of combustion, and the air being admitted above the green fuel, but below the fire, is thus well mixed with the gases liberated from the coking coal below the tuyeres. This combustible mixture of air and gases passing upwards to the burning fuel is nearly completely consumed, and very little smoke is made. This prevention of smoke is a great advantage in large cities.

As a result of the above arrangements, it is found that the amount of air required per pound of coal when burned with this stoker is from 20 to 55 per cent. less than that required with the common mechanical stoker. This effects a two-fold economy in decreasing the volume of heated gases escaping up the chimney, and likewise decreasing the velocity of the gases as they pass over the heating surfaces, thus allowing more time for the absorption of heat by the said surfaces. The economic use of air in this stoker compared with other mechanically-operated stokers is due to the unusual depth of coal carried, the air being supplied from beneath and the continuous action of feeding overcoming the tendency of holes burning through the fire. The disadvantages of this stoker are the expenses entailed in the installing and upkeep of the blower and the difficulty of cleaning the fires when compared with the ease with which the fires are kept clean when using the chain-grate type of stoker.—J. WALKER.

Question No. 628.—What is the best method of improving the draught in a central station which at present has a very poor natural draught?

Best Answer to No. 628 (*awarded* 10*s.*).—A poor draught depends on so many details, that I think in answering this question it will probably be best to consider the whole matter of draught more or less in detail.

Definition of Draught.—More or less confusion exists in the use of the term "draught" owing to its double meaning. As usually employed, it refers to the difference in pressure between the external air and the gases from the boiler, and is measured by the height of the column of water such pressure is able to sustain. Methods for making such measurements will, however, be dealt with further on. This difference of pressure is called the "intensity" of the draught, although sometimes referred to simply as the draught, and is directly proportioned to the height of the chimney and the difference in temperature of the flue gases and the exterior air. Again, "draught" is sometimes used in referring to the velocity which the intensity of "draught" (or difference of pressure, as above) has the power to create and the corresponding volume of air moved. Draught, as thus understood, is directly proportional to the sectional area of the chimney at the top and the square root of the height.

Intensity of Draught.—The object of draught is to pass a sufficient supply of air through the boiler grates for the efficient combustion of fuel, and to carry away the gases resulting from such combustion. To do this the draught requires to be of such intensity as to overcome the resistance offered to the passage of air by the fire, boiler tubes, main flue, chimney resistance, etc. The proportion of such necessary for overcoming these various resistances is approximately as follows—viz.:

For entrance velocity	0·003in.	of water.
Resistance of fire-grate	0·182in.	,,
,, of combustion chamber and boiler tubes	0·246in.	,,
,, of main flue	0·012in.	,,
For discharge velocity.....	0·017in.	,,
Total effective draught pressure	0·460in.	
Resistance of stack	0·040in.	
Total pressure of chimney	0·500in.	,,

Any pressure over and above this quantity will be available for giving such velocity to the gases as will draw the necessary amount of air through the grate for the effective combustion of the fuel. The quantity of air will, of course, vary considerably with the class of fuel, thickness of fire, etc.

Chimney Design.—There are several formulæ for the correct design of chimneys, the best, I think, being the following—viz.: where H = height of chimney; F = pounds of coal burned per hour; A = effective area of chimney; T_a = temperature of external air, 460; T_c = temperature of gases, 460; D = draught; then

$$d = h\left(\frac{7{\cdot}6}{T_a} - \frac{7{\cdot}9}{T_c}\right), \qquad h = \left(\frac{0{\cdot}0825\ F}{A}\right)^2.$$

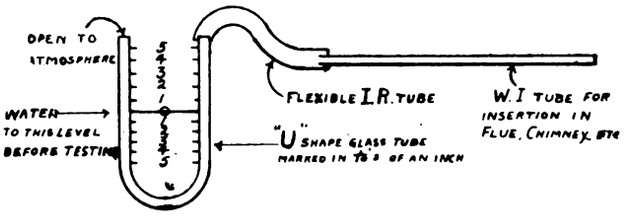
A well-designed chimney of about 150ft. should give a draught of 1in. water pressure with flue gases at 500deg. F. and an air temperature of 50deg. F. It has been found by experiment that the following minimum chimney heights are required for various classes and quantities of coal burned:

Class of coal.	Chimney height.	Coal consumed per hour.	Chimney height.
Free-burning coal (bituminous)	85ft.	1,000lb.	120ft.
Slow-burning bituminous	125ft.	2,000lb.	140ft.
Fine anthracite	130ft.-150ft.	3,000lb.	160ft.
Fine coal or slack	175ft.	4,000lb.	180ft.

Measurement of Draught.—Draught is usually measured by the difference in level of a liquid in the arms of a tube of U form, having one end open to atmosphere and the other connected with the flue or chimney, or wherever the draught is required to be measured. The preponderance of pressure in one arm forces the liquid downwards and causes a corresponding rise in the other. The difference in level represents the height of a column of the liquid which will be sustained by the pressure, and is measured on a scale graduated in one-tenth parts of an inch, as shown in sketch. This U-tube arrangement can be replaced

Digitized by Google

with excellent results by a direct-reading draught gauge, such as the "Ever-trusty," made by Wallach Bros.



Cause of Bad Draught.—Although the draught at the chimney root may be good, it can be absolutely spoiled by any of the following causes—viz, leakage of air through brickwork. At frequent intervals the whole of the brickwork forming the side and main flues, should be carefully tested for air leaks by means of an open flame lamp. On carrying out such tests, one will often be greatly surprised at the amount of air getting into a flue through cement joints, flue doors, and sometimes even through the solid brick. I have found such leaks causing a reduction in draught intensity of a full tenth of an inch. All these, of course, should be carefully stopped, and the whole flue brickwork occasionally repointed. Accumulation of soot is another item which has an extremely bad effect on the draught, especially when allowed to accumulate in the boiler flue tubes at back of fire arch. These flue tubes should be cleaned at least every three months and the main flue every six months. The draught will be increased thereby and coal saved. As to the construction of flues, they should be so constructed as to offer as little resistance as possible to the flow of the gases, and all sharp bends, abrupt change of cross-section, and sudden enlargements should be carefully avoided. A capacious flue means a low velocity of gases, and I have known of a small flue opening into one of almost twice the area causing a reduction in draught of 0·15in. water pressure. The main flue should not be less in area than the cross-section of the chimney at the top, and nothing is gained in making it much larger than this. The correct area is about one-seventh of the total fire-grate area. If the length of the main flue is great, the area of the chimney top will need to be increased. Counting this area as 1 for a 100ft. flue, then for any extra length of flue the dividing constant is: 100ft. = 1, 200ft. = 0·853, 400ft. = 0·708, 600ft. = 0·625; so that for a 200ft. flue the area would need to be increased in the ratio of $\frac{1}{\cdot 853}$. It is also desirable to have a damper in the main flue for cutting off every pair of boilers from the chimney, as otherwise considerable air may leak into the flue through badly-fitting dampers or boilers standing idle. Intensity of draught, as was above pointed out, depends on the height of the chimney, and cannot be altered except by increasing the height. A chimney for a works of any size should have a draught of at least from 0·8in. to 1in. of water pressure at the root under normal conditions of temperature and barometric height.

Remedies for Poor Draught.—If on testing the pressure at the root of the root of the chimney it is found to be good, the trouble must be looked for in the flues, and these should be tested and examined for the points of weakness detailed above, the remedy being applied in accordance with the finding of such examination, and as the construction of the flues under inspection will allow. On the other hand, if the intensity of the draught at the chimney root is found to be bad, the only remedy is to increase the height of the chimney, build another one, put a fan in the existing chimney, or use forced draught created by means of steam jets or supplying air under pressure to the underside of the grate. The possibility of increasing the height of the existing chimney will depend on the foundations, diameter at base, and the thickness of the brickwork at the top. As regards the foundations, these will usually be found sufficient, while to ensure the stability of the chimney the height should not be more than 12 times the diameter at the base. If the brickwork is less than 14in. at the top, it will be impossible to increase the height sufficiently to gain any increased efficiency thereby, as on no account should more than 25ft. of 9in. brickwork be erected, and if the chimney top is more than 6ft. diameter inside, no 9in. work should be allowed at all. Care must also be taken that in increasing the height the area of the chimney top is not contracted too much, as otherwise, if the chimney is working at full pressure, the benefit gained by the increased height will be lost. Whether the chimney top will stand diminishing or not can be arrived at with the aid of the formulæ given above and a knowledge of working conditions. The cost of heightening a chimney from, say, 100ft. to 150ft. is approximately from 35s. to 40s. per rising foot. If, then, the chimney is not 150ft. high, and the draught is poor, I would certainly advocate building to this height, providing the construction will allow. Beyond this height the expense of further increase is rarely justified by any additional efficiency obtained. If, however, the chimney is already 150ft. high, I would in preference to putting up another one (after proper consideration of existing conditions, of course) recommend the adoption of induced draught by means of a fan in the chimney, several excellent fans for the purpose being on the market at present. With such a fan any required draught can be obtained and regulated according to the class of fuel burned and the demand for steam, as boilers can be pressed easily and economically to 30 per cent. above their normal rate. Such being the case, if a fan is used, less boiler plant need be installed than would be necessary with natural draught. Economisers can be used with greater economy, as the reduction in the temperature of the gases will not affect the draught, and with this method you are independent of atmospheric conditions. One of the chief advantages is that a much cheaper class of fuel can be burned. The power taken by such fans is about 1·5 to 2 per cent. of the total output of boilers. There are also many excellent methods of forced draught, but in my opinion the induced-draught method is by far the best. Naturally, the cost and existing conditions would need to be considered in deciding whether to erect another chimney, or adopt any of these methods of improving a poor draught.—A. D.

Answer to No. 628 (*awarded* 7*s.* 6*d.*).—Unless a central station has originally been designed with very broad views as regards probable increased demand for power, the engineer has usually very soon to face the problem of what is the best means of increasing the output of the station. In this is frequently involved the question of providing a suitable draught of ample power to ensure efficient combustion. This may be accomplished in two ways: (1) by increasing the natural draught, (2) by adopting some form of forced draught. In the following remarks it must be understood that they are not intended as a comparison between natural and forced draught, but are merely made with a view to a solution of the present problem, which is to improve an existing inferior natural draught.

Taking, first, the case of natural draught. A defective draught may be improved by increasing the height of the chimney; or, if this is not practical, and ground space permits a second, and, if necessary, a larger chimney may be erected. Of course, the chimney itself may be of ample capacity and height, and yet only a poor draught obtained, owing to defective or badly constructed flues. Very frequently considerable improvement can be effected by giving proper attention to the flues. Turning now to forced draught, we will briefly discuss the various available systems. These may be divided into two classes—the steam jet and fan draught.

Steam Jet.—This consists of blowing air and steam by means of a steam jet into the furnace ashpit. This is accomplished with specially constructed blowers or nozzles, and the system possesses the great advantage of being low in first cost. It is, however, a very wasteful arrangement, consuming anywhere between 5 and 20 per cent. of the total steam produced. It may be generally accepted that steam jets should only be adopted when the station is of small capacity, comprising one or two boilers only. It is claimed for this system that when cheap fuel is used, there is a tendency to prevent the formation of clinker, owing to the decomposition of the steam into its constituent gases, hydrogen and oxygen. It is also very convenient, inasmuch as it can be easily regulated and shut off when the furnace door is opened for firing.

Digitized by Google

Fan Draught.—This is divided into two systems—forced and induced draught.

Forced Draught.—This system consists of the application of fans which supply air at a suitable pressure through specially constructed conduits to the boiler furnaces, which are arranged with closed ashpits. Among the advantages ascribed to this system are: (1) it can be very readily adopted to existing boiler plant; (2) convenient and efficient regulation of air supply; (3) no great inrush of air when the furnace door is opened, as the stoker can shut off the pressure; (4) less wear and tear on the fan than with induced draught. The principal objection is that there is a liability of holes being blown in the fire. This, however, can be obviated by suitably arranged dampers in the ashpit for distributing the air supply. The supply should always be completely cut off before the furnace doors are opened, or flames and dust will be blown about the stokehold.

Induced Draught.—In this system the fan or fans are placed in the boiler uptake, thus producing a draught similar to that effected by natural means. With this arrangement the draught may very readily be increased or decreased, as the demand for steam varies, without the danger of blowing holes in the fire. There is also no possibility of fire or dust being blown into the boiler-room, as in the case of forced draught. It is somewhat expensive in upkeep, owing to wear and tear consequent upon the fan being exposed to the hot gases. When firing there is a considerable rush of cold air into the furnace, as in the case of natural draught. The above is a concise summary of the various points in favour of or against the different methods of securing an efficient draught, and we will now briefly refer to the consideration governing a selection to meet present requirements.

Ground Space.—If the proposed extensions are of any magnitude, and the available space for new chimney, boilers, etc., is limited, it may be quite out of the question to so increase the natural draught and boiler plant to a sufficient extent. One outstanding advantage of forced draught is that the capacity of existing plant may be increased as much as 30 per cent. by its adoption, and where room is of first importance forced draught is probably the best way out of the difficulty.

Cost.—The first cost of installing a fan-draught system is low as compared with building of a large chimney when power approximates 1,000 h.p., and gets more favourable as the size of the station increases; but, of course, when the chimney is once erected its maintenance is not so great as the running expenses and upkeep of a forced draught system.

Fuel.—The class of fuel to be burned has a considerable bearing upon the question, inferior fuels requiring considerably more draught than do the better grades of bituminous coal, and sometimes an installation of forced draught becomes necessary solely on this account.

Size of Plant.—The case in point does not contain any idea of the size of plant. This is a very important matter in coming to a satisfactory solution, but it may be stated that, generally speaking, the advantage of fan draught becomes more apparent as the size of plant increases.

The above points are the principal considerations governing a selection of the best system under various conditions, but there are many others to which some consideration has to be given, such, for instance, as the existing arrangement of flues, economisers, conditions of existing chimney, and efficiency of present draught. In making a selection it must always be kept in view that mechanical draught is unaffected by climatic conditions.—F. A.

Answer to No. 628 (*awarded* 5*s.*).—The methods of improving a poor natural draught are either to induce a draught by a fan placed in the flue, which by removing the gases causes the pressure in the flue to be less than that of the atmosphere, or to produce a draught by forcing air into the furnaces. Both induced and forced draught may be obtained by using either fans or a steam blast. The usual way, however, where induced draught is used is to employ fans, as although in one or two instances in non-condensing plants the exhaust steam from the engines has been turned into the chimney shaft to assist the natural draught, it will be obvious that with a free exhaust no great assistance can be looked for in this direction, and a throttled exhaust is, of course, out of the question.

The methods in general use are: (1) forced draught obtained by using either fans or a steam blast; (2) induced draught produced by fans placed in the flues. The cheapest method to instal is forced draught produced by means of steam blasts. In one well-known system two steam blasts are generally fitted to each furnace of a Lancashire boiler. The ashpit is closed by an air-tight cover, and the blast admitted underneath the furnace by two nozzles. The steam blowing through these nozzles at a fairly high speed takes in with it a certain quantity of air, and thus creates a draught; this draught is delivered about half way up the underside of the furnace by a bell-mouthed tube, which assists in distributing the draught. On the outside of the airtight cover are placed two valves for regulating the supply of steam and air respectively. Low first cost, however, is about the only point this method has to recommend it.

The efficiency of the steam blasts being considerably less than that of fans, the amount of steam necessary being greatly in excess of that claimed by the makers, the boiler is also liable to suffer damage unless the steam used in the blasts is perfectly dry. The draught, in spite of numerous precautions, is also very liable to be concentrated in one or two places, resulting in burnt firebars and other delights due to the excessive heat produced. Forced draught as obtained at sea by means of a closed stokehold has proved itself to be highly successful, but on shore it is practically impossible to obtain a closed stokehold, so that this method need not be considered.

In the Howden system of forced draught, adapted for land purposes, the air is forced by fans through rows of vertical tubes, placed in a box through which the waste gases are led; the air is thus heated before being admitted to the furnaces. An arrangement is also made so that the firedoor cannot be opened before the draught is shut off, and thus one of the objections to forced draught—viz., the risk to the fireman of being burnt by opening the furnace door when the draught is on—is done away with. This system does not necessitate a closed ashpit, and the contention of the makers that the wear and tear on the boilers is diminished, has been found to be substantiated in practice. Messrs. Ellis and Eaves have a system of induced draught, in which the air before being drawn through the furnace is heated in a similar manner to that in the Howden system, except that the tubes are placed horizontally. The heated air is also, as in the Howden system, admitted to the furnace by suitable dampers either above or below the fire. This system is in use in several central stations, and has given excellent results.

To sum up, in the case of induced draught the fans have to work in the hot gases from the furnaces (which are also very gritty), and this necessitates them being more powerful than if they simply had to deal with cold air, as in the case of forced draught. The increase in power required to move a given weight of air, and to maintain a given difference of pressure with air at a temperature of 300deg. F., is nearly 50 per cent., as compared with air at a temperature of 50deg. F. There is also the risk with induced draught that cold air will be drawn into the flues at undesirable places, owing to leaks in the brickwork setting. The great drawback to forced draught, the afore-mentioned risk to the fireman, being capable of being obviated, the balance is in favour of using the Howden system of forced draught.—W. T. W.

Answer to No. 628 (*awarded* 5*s.*).—Before giving a definite answer to this problem which confronts a great many central-station engineers after a few years' working, it will be as well if we enquire into the causes of natural draught, and whether it will be wise to extend it, or to use either of the other two methods in use in central stations—namely, induced draught or forced draught (*i.e.*, draught caused by steam blowers at the front of the boilers). Natural draught is produced by a chimney, and is due to the difference in the weight of a column of hot air inside the chimney, and an equal column of cold air outside. The weight of a cubic foot of air at 62deg. F. is ·0761lb., the weight of a cubic feet of air at 552deg. F. is

Digitized by Google

·0393lb.—that is, practically one half its volume will be doubled. The air outside will, therefore, have a pressure to force it through the fires about twice the hot gases in the chimney possess. Note.—We are neglecting the slight differences in the specific gravities of air and the hot gases.

To determine what pressure—*i.e.*, the pressure as measured by a water-gauge at the bottom of the chimney—the above two temperatures will give with a chimney 140ft. high, we have

$$(\cdot0761 - \cdot0393)\ 140 = 5\cdot2\text{lb.}$$

Now, 5·2lb. is equal to the weight of a square foot of water 1in. high, so that the draught will be equal to the pressure of 1in. of water. From this formula, by assuming different heights and temperatures of gases in the chimney, it will be noticed that it requires a great increase in height to produce a much better draught, but this would be out of the question in certain localities, local authorities, as a rule, being prejudiced against high chimneys, and not only that, the foundations of the present chimney would probably require alterations as regards increasing the temperatures of the gases in the chimney—this would be very uneconomical, as possibly economisers would have to be done away with.

The best method of increasing the draught would be to put down an induced-draught plant, which consists of a fan with simple radial blades revolving in a steel casing fixed in the flues, usually at the bottom of the chimney; in revolving it drains the gases away from the boilers. The advantages of this method are numerous. Firstly, the maximum load in a central station lasts only for a short period of the day, during which you are enabled to work your boilers beyond their rated capacity without seriously reducing their economy; a less number are, therefore, required as stand-by. It is not necessary to have a large quantity of heat in the flue gases in order to keep up the draught, so that economisers and superheaters may be used with greater economy, and it might even be advisable to extend the former. The heat loss with natural draught is usually between 15 to 20 per cent.; with induced draught this may be reduced to two-thirds of this. It gives complete control in governing the fires—firstly, with different qualities of coal, the smallest (which usually works out the cheapest) can easily be burnt; secondly, in case of rapidly changing loads, due to fogs, etc. It is independent of atmospheric conditions. It is also independent of air leakages through brickwork of the flues. It is easily adapted to existing natural draught.

An induced-draught system must be properly designed. The fan must be large enough to give its maximum draught without being run at too high a peripheral speed. It may be driven either by an electric motor or steam-engine, which should be in duplicate, the power consumed being under 1 per cent. of total. The steam-engine may be made to govern automatically, so that if boiler steam pressure rises the fan runs slower, thus lessening the intensity of the draught and *vice versâ*. The initial cost will be considerably less than a new shaft, with its expensive foundations, flues, etc., in a 2,000-h.p. station, the chimney, etc., costing approximately £2,200, the fan complete £1,000, and the working costs will be about one-tenth of power represented by the waste heat in a good natural draught. The steam blast may be dismissed with a few remarks: it may be cheaply installed, but is very costly to work, not easily duplicated, and has the disadvantage that if the steam pressure falls, due to a sudden demand for steam, its efficiency falls too.—F. H. R.

PERSONAL.

We understand that Mr. Frank B. Cramer has left the International Electrical Engineering Company, where he held the position of technical manager, and has rejoined Messrs. Johnson and Phillips, with whom he was formerly associated for some years.

The Aston Tramways and Electric Light Committee have appointed Mr. Thomas J. Ballard, of Sheffield, resident electrical engineer, at a salary of £400 per annum.

On Wednesday Mr. W. W. Booker was presented at the electricity works, White Hart-road, Plumstead, with a handsome set of books from his late colleagues. He left these works, where he held the appointment of correspondence clerk, to take up a similar appointment in the electricity works of the borough of Hampstead, where we trust he will meet with every success.

The Frome Urban District Council have approved of the engagement of Mr. G. T. Pardoe as clerk of the electrical works at a salary of £180 per annum, the engagement to begin when Mr. Pardoe has completed his duties with the Fulham Corporation.

The Cardiff Town Council have increased the salaries of a number of officials in the electrical department.

Mr. H. E. Brown, an engineer at present in the employ of the Poplar Union, has been appointed second distributing assistant at the electricity department, at a salary of £120 per annum.

Mr. Thomas Holme, of the Portsmouth municipal telephone exchange, has been appointed manager of the Hull Corporation telephone undertaking, at a salary of £200, to be increased to £250 in the event of the expenditure not exceeding the amount of the loan.

Mr. Jack Hawes (late assistant engineer to the metropolitan borough of Bermondsey electricity and dust destructor works), having been appointed chief assistant electrical engineer to the firm of Messrs. Tyler and Duncan, has been presented with a dressing-case by Mr. A. E. Young, on behalf of the officials and staff of the above works, as an appreciation of his good services.

LEGAL INTELLIGENCE.

ISLE OF THANET TRAMWAYS.

In the case of Cole *v.* Isle of Thanet Electric Trams Company, Limited, before Mr. Justice Bigham and a special jury, in the High Courts, the plaintiff, a widow, recovered £200 for the loss of her husband, who was killed by one of the defendant company's cars in July, 1902.

His Lordship entered judgment in accordance with the finding of the majority of the jury (consented to by the parties), with costs, but granted a stay of execution, remarking that he did not think the verdict a right one.

SPEED OF TRAMCARS.

At the West London Police Court on Saturday, Mr. Rose again had before him the adjourned summonses against four drivers in the employment of the London United Tramways, Limited, for driving electric tramcars at more than 10 miles an hour, the limit laid down by the Board of Trade for the locality (Goldhawk-road, Shepherd's Bush) in which the offences were alleged to have been committed.

Prof. Silvanus Thompson now stated that since the last hearing he had made a careful examination of the company's mechanical and electrical plant, and of the four cars, and he had made four speed tests of each of the cars on the measured furlong used in Colonel Purcell's tests. The mean speeds attained by the cars were as follows: car No. 272, 14·465 miles per hour; No. 60, 12·487 miles; No. 75, 13·335 miles; No. 173, 14·157 miles. When he made these tests he had a voltmeter on the cars, and he was satisfied that the conditions under which the tests were made were fair, and that there had been no tampering of any sort or kind with the electrical plant or with the cars. In his judgment it was not possible for any of these cars to go at 17 miles per hour on the section of line referred to. In cross-examination, Prof. Thompson said it was not necessary to use a voltmeter for tests of speeds; the use of a voltmeter was only necessary when, as at the last hearing of this case, suggestions of fraud were made.

Mr. J. R. Salter, engineer-in-chief to the South Lancashire Electric Tramways, testified to the fact that the plant had not been tampered with. The conditions on the day Prof. Thompson made his tests were precisely the same as when Colonel Purcell's tests were made.

In giving his decision, **Mr. Rose** said it was clear that the methods by which Mr. Ford (the prosecutor) took the speeds were not so exact and accurate that he could have relied upon them if it had been alleged that the regulation speed per hour had been exceeded by, say, a quarter of a mile per hour. But after hearing the expert evidence he was not so satisfied of Mr. Ford's gross inaccuracy as to doubt his statement that the speed of the cars exceeded 10 miles an hour, although it appeared to be practically impossible that the cars could have attained the very high speeds which Mr. Ford alleged. If the speed exceeded 10 miles an hour there must be a fine, whatever the effect might be upon the public convenience. As to the amount of the fine, motorists would no doubt think that the same fine as they usually paid ought to be imposed on this great company; but it was not the company that was summoned, but the drivers, and he would impose fines of £2 each.

Mr. Muir said that Mr. Ford had in the course of the case made a deliberate suggestion of fraud against the company in connection with the tests, and he hoped the magistrate would express his opinion on that point.

Mr. Rose said he did not regard it as a suggestion of fraud.

Mr. Ford said he had not intended to make such a suggestion; if he had made it, he withdrew it.

DEFINITION OF A WORKMAN.

The case reported in our last issue, in which the Leeds Stipendary was called upon to define "a workman" in connection with the issue of workmen's fares on the electric tramways, was again before the magistrate on Wednesday. The Corporation summoned an estate agent's clerk for refusing to pay more than the workman's fare when travelling on a car intended for the carriage of workmen.

Digitized by Google

The **Magistrate**, after a lengthy hearing, said that, inasmuch as it was admitted that this was a car run under the section in the Corporation Act relating to workmen's cars, the Corporation had no authority to demand from the defendant more than the penny which he offered to pay, because, whatever might be said about mechanics, artisans, or daily labourers, it provided that these cars should be run at tolls not exceeding ½d. per mile, and that the Corporation should not be required to take any toll or charge less than 1d. It was admitted that this was a car run under this section, and it was not open to the Corporation to demand the same toll as for an ordinary car. Inasmuch as the defendant was accepted as a passenger, and was not removed from the car or asked to leave, the only legal charge the Corporation could make was the penny tendered.

The case was dismissed, and the defendant was allowed 5s. cost.

A TELEPHONE AGREEMENT.

The National Telephone Company, at the Cardiff County Court, sued Mr. David Mullins for the recovery of 13s. 7d. in respect of telephone fees.

The **Company's Manager** said defendant signed a "party-line agreement." There were five subscribers on the line, and they agreed to pay 2d. per day. Under that agreement 13s. 7d. was due.

Mr. George David (for the defendant): You have had frequent complaints with regard to this instrument?—Yes, one or two.

Mr. David: You know they have been absolutely unable to use it?

The Judge: That's a matter for a counter-claim.

Mr. David: No, your Honour; there is an implied condition that they must supply us with an instrument that is fit for the purpose.

Plaintiff's Manager said the defendant's premises were connected on Dec. 24 last, and the instrument was paid for regularly up to May 16. There was then 3s. 7d. outstanding, and as this was not paid the line was disconnected on May 28.

Mr. David: Although they disconnected us their charges are running on.

Witness: The agreement provides for that. The instrument is still there.

The Judge: If you cut off a man's water, you cannot charge for it afterwards. I will certainly not enforce that part of your agreement unless I am compelled to. All you can recover is 2d. per day up to May 28. His Honour, having examined the agreement, gave judgment for the defendant.

GREENOCK TRAMWAYS.

We have received an official copy of the arbitration proceedings and award in the dispute between the Greenock and Port Glasgow Tramways Company and the Greenock Corporation as to what were the obligations of the former to take electrical energy from the Corporation for the working of the tramways. The agreement between the parties stipulated that the company were to take from May 1, 1901, all the energy required for the working of the tramways, the minimum amount guaranteed by the company being 500,000 units per annum. The price to be paid by the company for this energy was 1½d. per unit for the 500,000; the price of all energy in excess of this amount to be settled by mutual agreement. A further condition of the lease was that the company were to pay the Corporation a reasonable sum for the use of feeder ways. Owing to differences arising between the Corporation and the company an appeal was made as provided by the lease by the company to the Board of Trade, who appointed Mr. Sheldon, barrister, to act as arbiter between the two parties. The questions submitted to him were: first, to determine the date from which the company were bound to fulfil their obligation to take electric energy from the Corporation at the rate of 500,000 units per annum; second, the price to be paid by the company for all energy in excess of 500,000 units per annum; third, the sum to be paid as rental for the use of cableways, the capital value of which was admitted to be £2,000.

The sittings of the arbitration court took place in the Inns of Court Hotel, Mr. Sydney Morse representing the company (which is one of the British Electric Traction group), while Mr. John Kennedy represented the interests of the Corporation.

The most important of the three questions was, of course, that referring to the price to be paid for the energy in excess of the 500,000 units. The Corporation called Mr. J. A. Robertson, burgh electrical engineer, to give evidence as to the present condition of the undertaking, and the cost of producing energy for the company. He was cross-examined by Mr. Sydney Morse, who tried to show that the cost of producing traction energy in a combined station was much less than the cost of producing lighting energy, and that it was unfair to divide the costs of production equally over the whole output. The Corporation also called Mr. I. E. Winslow, of the New General Traction Company, who gave it as his opinion that no reduction should be made in the price charged for energy until the company's consumption reached a million units per annum.

The company called Mr. H. M. Sayers, Mr. A. J. Lawson, Mr. Arthur Wright, and Mr. Phillip Dawson. These witnesses were all of opinion that the excess power should be supplied at the rate of ½d. per unit. As the company are taking energy at the rate of nearly 800,000 units per annum, it will be seen that the difference between the company's figures and the price asked by the Corporation would amount to over £1,200 per annum.

The arbiter's award is as follows: first, the 1st of August, 1901, is the date from which the company were bound to take energy at the rate of 500,000 units per annum; second, that seven-tenths of a penny is the price to be paid for all energy in excess of the minimum guaranteed amount of 500,000 units per annum; third, that £125 per annum is the sum to be paid for the rent of the cableways used by the company for their traction feeders.

The costs of the arbitration are to be borne equally by each party.

COMPANIES' MEETINGS AND REPORTS.

EDISON AND SWAN UNITED ELECTRIC LIGHT.

The ordinary general meeting of the shareholders in this Company was held at Winchester House, E.C., on Thursday last week, Mr. Henry Wolfenden presiding.

The **Chairman**, in moving the adoption of the report (which appeared in our issue for the 30th ult.), said that the directors were sorry that they had not been able to hold the meeting at an earlier date. The great amount of detail involved would prevent the meeting being held before October, which he hoped would be the month in future. The shareholders would notice that the report was drawn up in a different manner to those of former years. A detailed profit and loss account was not shown, but only the balance of net revenue was stated. That course the directors thought was the right one in the interests of the Company. The sales for the year showed a decrease, but the deficiency in that direction was more than recouped by a reduction in expenses. The sales since last June showed an improvement over those for the corresponding period of last year. The balance had been arrived at after the present stock had been valued on conservative lines. He confidently believed that no further reduction of the prices of stocks would be likely, unless something extraordinary should arise, such as a heavy fall in the cost of production, etc., which, however, he did not look for. Some shareholders might think that the directors had put too freely to depreciation of plant, but the Board was in the best position to decide. The Board had added £1,000 to reserve for future stock depreciation. When that reserve reached a higher figure, the question would be reconsidered as to whether it should be added to annually. The investments, consequent upon the sales of National Telephone shares, were reduced. The indebtedness of the Altrincham Electric Supply Company was reduced by £151, and he expected that the process of reduction would continue during the current year. That undertaking was making steady progress. With regard to the possibility of reducing the capital of the Company, it did not appear to the directors that any good could be obtained at present by writing it down. He sympathised with the shareholders that the directors were not in a position to declare a dividend. The Company was making steady progress, and he looked forward to the future with confidence.

A **Shareholder** asked if the Company was holding its own in regard to competition, and whether the stocks were down to bedrock. He also said that the question of reconstruction nowadays was so easy that it ought to be dealt with at once.

The **Chairman** said that he was satisfied that the Company could compete in lamps, quality considered, with anyone. The stocks were valued down to bedrock. As to the writing down of capital, the directors would act upon any mandate given by the shareholders, but in a short period the directors would be better able to see what was required.

The report was adopted.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH.

The report of the directors for the half-year ended June 30 states that the gross receipts amounted to £265,099, against £283,856 for the corresponding half-year of 1902. The working expenses, including £29,613 for maintenance of cables, absorb £138,516, against £121,237 for the corresponding period of 1902, leaving a balance of £126,582. From this is deducted £5,955 for income tax and £11,771 for interest on debenture stock, etc., leaving £108,856 as the net profit for the half-year. After adding £37,180 brought forward there is an available balance of £146,036. Two quarterly interim dividends of 1¼ per cent. each, amounting to £75,000, have been paid for the half-year, leaving a balance of £71,036 to be carried forward. The agreement concluded with the Australian Federal Government for extending to Melbourne and Brisbane the privilege enjoyed by the Company in other State capitals of Australia of dealing direct with the telegraphing public has been formally approved by the Federal House of Representatives, but the Senate has deferred coming to a definite decision upon it pending the result of a conference to be held between the interested Governments to consider what effect the agreement may have upon the British Pacific Cable, and other questions. Meanwhile the tentative arrangement come to with the Federal Government, by which the Company is allowed to work a special wire between Adelaide and Melbourne, and to deal direct with the public in the latter city, remains undisturbed.

NEW COMPANIES REGISTERED.

Electro Peat-Coal Syndicate, Limited (79,016)—Capital, £500. Object: to carry on the business of manufacturers of peat-fuel, peat-charcoal, and fibrous peat, etc.

Alert Electrical Company, Limited.—Capital, £2,000. Object: to carry on the business of electricians, electrical engineers, producers, generators, accumulators, etc.

Light Cure and Electro-Therapeutic Institute, Limited.—Capital, £12,000. Objects: to provide, furnish, and maintain an establishment for the cure and relief of diseases and ailments by electrical and other kindred treatment, etc.

Sunderland District Electric Tramways, Limited (79,054).—Capital, £270,000. Objects: to acquire the right to construct a tramway or tramways in the neighbourhood of Sunderland, etc.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Erith.—The Council invite tenders for the wiring and fitting of premises.

Newport (Mon.).—The Borough Council invite tenders for three 50-h.p. motors, etc., by 23rd inst.

Whitehaven.—The Guardians require tenders for the lighting of their infirmary. Tenders by Nov. 18.

Middlesbrough.—Tenders are required by the Corporation for dynamos, boilers, and condensers, by 28th inst.

Brussels.—The Belgian State Railways require tenders for four lots of telegraph poles (specification No. 217). Tenders by Dec. 23.

Canosa di Puglia (Italy).—The Municipality will receive tenders for installing and working electric lighting for 50 years. Tenders by 30th inst.

Witton (Birmingham).—Messrs Kynoch, Limited, invite tenders for electrical supplies for six or 12 months from Jan. 1, 1904. Tenders by 20th inst.

Hornsey.—The District Council invite tenders for one 300-kw. steam dynamo to be delivered in October, 1904, and another in March, 1905.

Dudley.—The Guardians invite tenders for the supply and fixing of the various appliances for the electric installation to the laundry and boiler house.

Windsor.—The Town Council invite tenders for the supply of electricity or gas for the purpose of public lighting throughout the district for a period of five years.

Wood Green.—The Urban District Council invite tenders for the erection of a power station and the buildings in connection with the Council's electric lighting scheme.

Leeds.—The Street-Lighting Department invite tenders for installing a heating plant at the new offices and workshops at Springwell-street. Tenders by noon on 16th inst.

Rangoon.—The Municipal Committee have decided to call for amended tenders for the electric lighting of the town on a continuous-current system. Five tenders were received for the first call.

Plymouth.—The Corporation invite tenders for painting, etc., tramcars. Specification, etc., can be obtained from the Tramways Manager, Ebrington-street, Plymouth. Tenders by 16th inst.

Greenwich.—The London County Council invite tenders for the supply delivery, and erection of four 3,000-kw. generators with exciters. Tenders by 10 a.m. on Dec. 8. See advertisement.

Wisby (Sweden).—Tenders are invited for a private and public electricity supply estimated to cost 180,000 kroner. Particulars may be obtained from the Director of the Draetselkammaren at the above place.

King's Norton and Northfield.—The Council invite tenders for the erection of car-sheds and waiting room. Tenders by 30th inst. to Mr. Edwin Docker, clerk to the Council, 10, Newhall-street, Birmingham.

London County Council Tramways.—The Council invite tenders for the wiring and fitting for electric lighting of five sub-stations and three car-sheds in connection with the tramways. Tenders by Dec. 5. See advertisement.

Sydney (N.S.W.).—Tenders are asked for the supply of continuous and alternating current meters. Specifications, conditions, and forms of tender are obtainable from Messrs. Preece and Cardew, 8, Queen Anne's-gate, S.W. See advertisement in last issue.

London, W.—The Great Western Railway Company invite tenders for the supply, delivery, and erection of water-tube boilers, engines, three-phase generators, and auxiliary plant at Park Royal, near Acton. Tenders by Dec. 7. See advertisement in last issue.

Kirkcaldy.—The Corporation invite tenders for one about 400-kw. combined steam-engine and dynamo for lighting or traction (vertical triple-expansion or three-crank compound and multipolar generator). Tenders by Nov. 23. See advertisement in last issue.

Christchurch (New Zealand).—Tenders are invited for the complete installation of electrical tramways, other than buildings. Specifications, etc., may be obtained from the Agent-General for New Zealand, Victoria-street, S.W. See advertisement in last issue.

Dartford.—The Metropolitan Asylums Board invite tenders for installing a complete system of telephones at the Darenth Asylum, Dartford, Kent. Specifications, etc., may be obtained at the office of the Board, Embankment, E.C. Tenders by 10 a.m. on Nov. 17.

Glasgow.—The Corporation invite tenders for the electric light installation, etc., for Anderston District Library. Specifications, etc., may be obtained from Messrs. Paterson and Stewart, architects, 14, Blythswood square, Glasgow. Tenders by 10 a.m. on 17th inst.

London, N.—The Hornsey Urban District Council invite tenders for the supply of meters, indicators, and consumers' fuse boxes. Specifications, etc., may be obtained from Mr. Norman Staniland, Electricity Works, Tottenham-lane, Hornsey. Tenders by 30th inst.

Todmorden.—The Corporation invite tenders for one Lancashire boiler, two steam dynamos and balancer booster, two feed pumps and one injector, economiser, surface or jet condenser, switchboard and instruments, storage battery, cable work, and overhead hand crane.

Blackadon (Devon).—The Corporation invite tenders for fitting up an electric light installation at the borough asylum. Specifications, etc., may be obtained from Mr. E. G. Okell, borough electrical engineer, Electricity Works, Prince Rock, Plymouth. Tenders by Nov. 14.

Dublin.—The United Tramways Company invite tenders for the supply of general stores, including car fittings, iron, steel, castings, oils, paints, glass, brushes, ironmongery, harness materials, electrical supplies, timber, etc., for year ending Dec. 31, 1904. Tenders by 30th inst.

Barrow-in-Furness.—The Corporation invite tenders for the completion of the electric lighting installation at Hawcoat and Walney police stations and the pig slaughtering hall and lairage at the public abattoirs. Further particulars may be obtained from the Borough Engineer.

Kilmarnock.—The Corporation invite tenders for three Lancashire boilers, engines and dynamos, overhead hand travelling crane, storage battery, switchboard. Specifications, etc., can be obtained from the Town Clerk. Tenders must be delivered at the Town Clerk's Office by Nov. 18.

Belfast.—The Committee invite tenders for the supply and erection of a complete heating and ventilating system, including steam boilers, heaters, etc., engines, blowers, and electric fans. Tenders by Dec. 4 to Messrs. Young and Mackenzie, architects, Scottish Amicable Buildings, Belfast.

Swindon (Wilts).—The Corporation invite tenders for complete traction switchboard cables, etc. Specifications, etc., may be obtained from Messrs. Lacey and Sillar, 78, King-street, Manchester, and 2, Queen Anne's-gate, Westminster. Tenders by Nov. 23. See advertisement in last issue.

Brighton.—The Council invite tenders for six water-tube boilers; a system of steam, exhaust, feed, blow-off, and suction pipes; and cast-iron storage tanks. Specifications, etc., may be obtained from Mr. Francis J. Tillstone, Town Hall, Brighton. Tenders by Dec. 7. See advertisement in last issue.

Warrington.—The Cheshire Lines Committee invite tenders for telegraph materials, steel fishplates, creosoted sleepers and crossing timbers, and oak keys. Specifications, etc., can be obtained from Mr. S. Saxon Barton, stores superintendent, Cheshire Lines, Warrington. Tenders by 10 a.m. on 27th inst.

Swindon.—The Corporation invite tenders for the supply, delivery, and erection of steel poles, overhead line section boxes, arc lamps, and accessories. Specifications, etc., may be obtained from Messrs. Lacey and Sillar, 78, King-street, Manchester, and 2, Queen Anne's-gate, Westminster. Tenders by Nov. 16.

Culiacan (Mexico).—Tenders are invited for lighting the town by electricity; 60 arc lamps of 1,200 c.p. and 110 incandescents of 50, 30, and 16 c.p. will be required. Propositions will be received by letter until Dec. 31 in the Secretaria del Ayuntamiento, Culiacan, where further information may be obtained.

Edinburgh.—The Lord Provost, Magistrates, and Council invite tenders for the wiring and fittings for the electric lighting installation at Gayfield-square police station. Specifications, etc., can be obtained at the office of the Resident Electrical Engineer, Dewar-place, Edinburgh. Tenders by 10 a.m. on 21st inst.

Radcliffe.—The Council invite tenders for the supply and completion of (Contract No. 12) lighting and traction switchboard and accessories; (14) rail bonds. Specifications may be obtained from Messrs. Lacey and Sillar, 2, Queen Anne's-gate, Westminster, and 78, King-street, Manchester. Tenders by Nov. 14.

Blackpool.—The Electricity and Tramways Committee invite tenders for one new 450-kw. traction set (vertical triple-expansion engine and multipolar generator). Specification may be obtained from Mr. Charles Furness, borough electrical and tramways engineer, Electricity Works, Blackpool. Tenders by Nov. 14.

Glasgow.—The Directors of the Caledonian Railway Company invite tenders for the supply of telegraph appliances, etc., and electric lighting material and fittings. Specifications, etc., may be obtained from Mr. Jas. Lorrimer, stores superintendent, Caledonian Railway, Charles-street, St. Rollox, Glasgow. Tenders by 23rd inst.

Handforth (near Manchester).—The Guardians of Chorlton-upon-Medlock Union invite tenders for an electric motor for the new laundry at Styal Cottage Homes, Handforth, near Manchester. Specifications, etc., can be obtained from the consulting electrical engineer, Mr. G. R. Peers, A.M.I.E.E., 16, John Dalton-street, Manchester.

Radcliffe (Lancs.).—The Urban District Council invite tenders for the supply of the pitch and oil required in the construction of the tramways in the district. Specifications, etc., may be obtained on application to Mr. W. L. Rothwell, engineer, at the Council Offices. Tenders to Mr. S. Mills, clerk, Council's Offices, Radcliffe, by Nov. 14.

Wednesbury.—The Corporation invite tenders for the electric wiring and fittings for the town hall, municipal offices, art gallery, public baths, public library, and electricity sub-station. Specification, etc., may be obtained at the offices of Mr. F. J. Warden-Stevens, A.M.I.M.E., A.M.I.E.E., 34, Victoria-street, Westminster, London, S.W. Tenders by noon on Nov. 20.

Manchester.—The Tramways Committee invite tenders for hard-drawn copper trolley wire for overhead equipment, galvanised steel span wire and span-wire brackets, and feeder straps for tramway poles. Specifications, etc., may be obtained on application to Mr. J. M'Elroy, Tramways Department, 55, Piccadilly, Manchester. Tenders to Chairman, Tramways Committee, by 17th inst.

Harrogate.—The Corporation Electricity Department invite tenders for the supply and part laying of two high-tension concentric, paper-insulated, lead-covered trunk mains from the electricity works to the town. Specification may be obtained from Mr. Geo. Wilkinson, M.I.M.E., M.I.E.E., engineer-in-chief, Corporation Electricity Department, 33, Swan-road, Harrogate. Tenders by Nov. 16.

Sydney (New South Wales).—Tenders will be received at the office of the Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 30, for the supply and delivery at the departmental stores, Sydney, of telegraph, telephone, and electric light

Digitized by Google

material. Specifications, etc., may be seen and tender forms obtained at the General Post Offices, Sydney, Melbourne, Brisbane, Adelaide, Hobart, and Perth.

Wednesbury.—The Corporation invite tenders for the electric wiring and fittings for the following public buildings: town hall, municipal offices, art gallery, public baths, public library, and electricity sub-station. Specification, etc., may be obtained between 2 and 5 p.m. at the offices of Mr. F. J. Warden-Stevens, A.M.I.M.E., A.M.I.E.E., consulting engineer, 34, Victoria-street, Westminster. Tenders by 12 noon on Nov. 20.

Colombo (Ceylon).—The Government of Ceylon invite proposals from persons willing to enter into a contract for the supply of electrical energy to the various offices, buildings, and premises of the Government, within the Municipality of Colombo, for a term of years commencing on or about Aug. 1, 1905 Proposals must be delivered at the office of the Colonial Secretary, Colombo, by Dec. 1. The *Ceylon Government Gazette* containing above notice may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament-street, S.W.

RESULTS OF TENDERS.

St. Helens.—The Corporation have placed an order with Dick, Kerr, and Co., Limited, for a 400-kw. direct-current generator.

Hong Kong.—Messrs. Johnson and Phillips of Victoria Works, Old Charlton, Kent, have secured the contract for the 250-kw. steam alternator for the Hong Kong electric light station.

Chesham.—The Council have accepted the tender of the electric light company to light the market-house clock, the fire station, and the lamp outside, for a sum of £13. 13s. per annum.

Aberdeen.—The Parish Council have accepted the tender of Messrs. Pratt and Keith for the electric installation at the new poorhouse, amounting to £2,001, subject to the architects being satisfied with the schedule.

British Aluminium Company.—This company has placed an order with Dick, Kerr, and Co. for two 520-kw. direct-current generators. The machines are for the Aluminium Company's works at Foyers, N.B., and are to be driven by turbines.

Sub-Contracts.—Messrs. Belliss and Morcom, Limited, report the following contracts: Reigate: By the General Electric Company, Witton, one engine for coupling direct to General Electric single-phase alternator. Dewsbury: By Messrs. Siemens Bros. and Co., Limited, one 500-h.p. engine for coupling direct to Siemens generator. North Riding Asylum, York: By Messrs. Crompton and Co., Limited, one engine for direct coupling to Crompton multipolar dynamo. Gravesend: By the British Westinghouse Company, one engine for direct coupling to Westinghouse generator.

Condensing Plant.—The Mirrlees-Watson Company, Glasgow, report the following orders for condensing plant: Yorkshire Power Scheme, per Babcock and Wilcox, 3 sets; Lancashire Power Scheme, per Babcock and Wilcox, 4 sets; Tokio Tramways, per Dick, Kerr, and Co., 2 sets; Watson's Paper Mills, per Willans and Robinson; Wouldham Cement Company, 2 sets; Govan Corporation, 3 sets; Metropolitan Tramways, per Brush Company, 5 sets; Clyde Valley Power Company, per Westinghouse Company, 2 sets; Hong Kong, per Brush Company, 2 sets; Bromley, per Edmundson's Corporation; Bradford Corporation, per J. Musgrave and Sons; Isle of Man, per Babcock and Wilcox; British Thomson-Houston Company, Rugby, etc. The condensing plant orders booked during the current year are to deal with over 1,000,000lb. of steam, or, say, 65,000 h.p., and the average horse-power dealt with per set is rather over 1,600 h.p.

Canterbury.—The Urban Sanitary Authority have received the following tenders for the supply of 2,200 yards of ·4 square inch t c/c cable:

Siemens Bros. and Co., York Mansion, York-street, Westminster, S.W. (accepted)	£1,290	0	0
Land and Sea Cable Works, 27, Mincing-lane, E.C.	1,283	7	0
British Insulated and Helsby Cables, Limited, Prescot, Lancs.	1,308	0	0
W. F. Dennis and Co., 49, Queen Victoria-street, E.C.	1,320	0	0
Callender's Cable and Construction Company, Limited, Hamilton House, Victoria-embankment, E.C.	1,331	0	0
W. T. Glover and Co., Limited, Trafford Park, Manchester	1,334	7	6
Western Electric Company, Limited, North Woolwich	1,372	0	0
Burley and Strange, Folkestone	1,383	13	3
W. T. Henley's Telegraph Works Company, Limited, Blomfield-street, London-wall, E.C.	1,395	0	0
Johnson and Phillips, Old Charlton	1,453	0	0
St. Helens Cable Company, Limited, Warrington	1,495	0	0
Union Cable Company, Limited, 23, College-hill, Cannon-street, E.C.	1,699	0	0
R. F. Heath, 47, Dawes-road, Fulham, S.W.	2,000	0	0

BUSINESS NOTES.

TRACTION.

Newcastle.—The Town Council have finally decided not to construct the line to Heaton.

Ashton.—The Wigan Corporation tramways to Ashton are now being proceeded with rapidly.

Belfast.—A meeting of the Council in committee has approved the draft of the proposed Tramways Bill.

Ipswich.—A successful trial has been made over one of the completed sections of the electric tramways.

Liverpool.—At the last meeting of the City Council it was decided to increase the membership of the Tramways Committee to 19.

London-Brighton Electric Railway.—It is stated that the London-to-Brighton electric railway project is postponed for the present.

St. Marylebone.—The Borough Council are recommended to adhere to their previous decision against the construction of surface tramways in Edgware-road.

Manchester.—The Corporation intend to promote a Bill in the next session of Parliament to authorise the construction of further lines of tramways in the city.

Dudley.—The tramway company are negotiating with the Corporation for the acquisition of more space in the Market-place for the development of the tramway system.

Sutton Coldfield.—A sub committee has been appointed to confer with the City of Birmingham Tramways Company on the question of the construction of tramways within the borough.

Richmond.—The proposed tramway extension to enable the electric cars to pass over Kew Bridge has again been discussed by the Richmond Town Council, the proposal being finally negatived after a spirited debate.

Wednesbury.—A special meeting of the Town Council has decided to give notice to the South Staffordshire Tramways Company requiring the company to sell to them so much of the tramway undertaking as is within the borough.

Llanelly.—The Borough Council have confirmed their decision to promote a Bill in Parliament to compel the British Insulated Wire Company to carry out their contract in reference to establishing a system of electric traction in the town.

Newport (Mon.).—It is stated that the Tramways Committee have yielded to the many protestations against the construction of a tramway on Stow Hill, and are prepared, when the necessary powers have been obtained, to run a motorcar service instead.

Colne.—The Colne and Trawden Light Railway Company intend to make an application to the Board of Trade for an extension of the time in which to complete the light railway No. 2, from the top of Heifer-lane to the terminus, and No. 3 from the borough boundary to the Rock Inn, Trawden.

Bettws-y-Coed.—At the monthly meeting of the Urban District Council it was reported that Messrs. Mansfield and Co., of London, proposed, on behalf of a syndicate, to proceed for powers to construct an electric railway from Corwen to Bangor. The Council decided to apply for full details of the scheme.

Cardiganshire.—The County Council, who had promised £18,000 towards the Aberystwyth-to-Aberayron light railway, have now given the promoters six months' extension of time for raising the capital. It was decided at the last meeting to contribute towards the cost of preparing a scheme for a line from Lampeter to Aberayron.

Raworth Motor and Control.—The new electric motor and control designed by Mr. A. Raworth, jun., on his regenerating system was tried on the Devonport and District Tramway Company's lines last week. No figures are as yet available on the subject, but the inventor claims considerable savings from the use of his system.

Rochester.—Mr. C. H. Merz has submitted a report to the City Council as to the construction of tramways along the New-road and Star-hill at once, instead of waiting for the main drainage scheme to be completed. Inasmuch as the scheme of drainage will not interfere with the construction of the tramways, the work is to be proceeded with at once.

North Lincolnshire.—The scheme for constructing a light railway from Frodingham to Winteringham Haven on the Humber, which has been in abeyance for some considerable time, has lately been resuscitated, and it is stated that the contracts will shortly be let and the work commenced. The estimated cost is £80,000, and the line will be about eight miles long.

Electro-Pneumatic Signalling.—The Great Central Railway Company, in addition to equipping their Woodhead tunnel with the Miller electric signals have, it is stated, now also placed a contract for the equipment of their main line at Manchester with low-pressure pneumatic signalling plant. The work will be carried out by the British Pneumatic Signalling Company.

Rochdale.—A meeting of the representatives of the various authorities concerned in the acquisition of the Bury, Rochdale, and Oldham Tramway Company's undertaking was held at Rochdale on Friday. The meeting unanimously resolved to request the Board of Trade to urge upon Sir Frederick Bramwell, the referee appointed by them, to proceed with the arbitration at the earliest date.

Wolverhampton.—The Board of Trade have conditionally approved of the Lorain system for the routes to be converted, subject to requirements which may be considered necessary on the inspection of the completed work. Speaking on the Tramway Committee's report at the last meeting of the Town Council, Alderman Mander explained that they had accepted tenders for six new cars at £570 less than they had cost before.

Liversedge.—Complaint was made at the last meeting of the Urban District Council that the electric traction company were not carrying out their obligations, so far as regarded the widening of the road at Millbridge and the continuation of the existing line to the top of Hightown. In regard to the first matter it was suggested that the Board of Trade should be written to, and be asked to compel the company to carry out their promise.

Kirkcaldy.—The Corporation provisional order to be lodged for the ensuing session of Parliament relates to the doubling of certain portions of the existing tramway line, alternative routes to High-street,

Digitized by Google

and a new tramway line from the cottage hospital to Dysart, partly in the burgh of Kirkcaldy and partly in the parish of Dysart. Power is also asked to provide or run omnibuses to and beyond any of the termini of the tramways or in connection therewith.

Aston.—The District Council have made arrangements with the Council of the city of Birmingham to supply them with electrical energy until 1906 for the purpose of running their cars between the Old Square and the Council's boundary, at the rate of 1½d. per unit, the city of Birmingham contributing £200 towards the cost of laying the necessary cables. The engineer has been instructed to give the contractor notice to commence the reconstruction of the tramways.

Llandudno.—A special meeting of the Urban Council has been held to consider whether the Council should give notice of an application for a provisional order for powers to lay down electric tramways in the district. Several members expressed the opinion that the Colwyn Bay Light Railway Company had made a very substantial commencement of their undertaking, and it was decided to defer until March next the question of whether the Council should seek tramway powers.

Lancashire and Yorkshire Railway.—In connection with the electrification of the Southport-Liverpool line on the Lancashire and Yorkshire Railway it has been decided to carry out the electrification as far as Crossens, and the work has been commenced. The triangular line which touches Chapel-street Station, Southport, is to be electrified, so that a train may pass from the northern end of the line at Crossens through St. Luke's Station and Birkdale direct to Liverpool. On the line from Southport to Liverpool the work is well advanced.

South Hams Light Railway.—The Light Railway Commissioners resumed in London on Friday the enquiry respecting the proposed light railway in the South Hams district, particulars of which were given in our last issue. Counsel announced that an agreement had been arrived at between the promoters and the Great Western Company, and the former had consented to so alter the scheme as to meet with the approval of the railway company. On the suggestion of Colonel Boughey the promoters will take time to consider the question of gauge.

Swansea.—At a meeting of the Corporation Electric Lighting and Tramways Committee the scheme for the construction of tramway extensions to the outlying districts of Morriston, Sketty, and Port Tenant was described in detail, and the tenders received for the construction of the lines were opened and considered. They numbered 30, and it was agreed to refer them to the sub-committee for classification, and the selection of three tenders for further consideration. The firms selected will be asked to specify the extra charges for laying the electric lighting cables in trenches opened from the tramway cables if desired.

Brighton.—A singular position has arisen in connection with the projected tramway extension along the Preston-road at Brighton. Under the Act of Parliament 38 members of the Council must vote on the question, but though a majority in favour of the scheme has twice been obtained, its opponents have now triumphed for the time by refusing to vote at all. The effect of their action has been to reduce the voting strength of the Council to less than 38, so that if the opponents persist in a course of action which the tramway advocates contend was never for a moment contemplated by the Act the majority will be in the curious position of being defeated by the minority. The estimated cost of the scheme is £18,000.

Torquay.—It will be remembered that after lengthy negotiations with the Dolter Traction Company the Town Council decided to adopt the system of traction which that company are exploiting. The company, needless to say, were anxious to obtain the concession, but, curious as it may seem, they have now informed the Corporation that they have decided "to abandon the business," on the plea that the terms proposed by the Corporation are not such as it was possible for business men to accept. In a letter to the secretary of the company, the town clerk of Torquay refuses to accept this explanation "as the real cause for abandoning the business." The Corporation would now be well advised to proceed with the scheme themselves.

Additional Traffic Returns.—Anglo-Argentine, £2,113 increase; Barcelona Ensanche y Gracia, £117 increase; Barcelona, £209 decrease; Brisbane, £77 increase (month of August, £11,736, increase £294), British Columbia Electric (month of March), gross earnings £10,352, net income £2,659; Buenos Ayres and Belgrano Electric, £89 decrease (month of October, £14,055, increase £1,002); Calcutta, £366 increase; Cape Town (month of September), receipts £15,174, expenditure £8,503; Isle of Thanet Electric, £4 increase; Lisbon Electric (month of September), receipts 89,636 milreis, expenses 51,231 milreis; Mexico Electric (month of August), receipts £48,600, expenses £27,900; Perth Electric, £267 increase; Port Elizabeth (month of September), receipts £3,730, expenditure £2,767.

Paisley.—Operations in the burgh in connection with the construction of the electric tramways have been resumed. Last week we stated that Sheriff Lyell had issued an interim interdict against the work being proceeded with, pending the settlement of the dispute as to the quality of granite setts to be used. On behalf of the tramways company an appeal was lodged against this decision, and the sheriff has now recalled the interim interdict, but continues the injunction as regards the relaying of whin setts on the roadways. The general effect of the decision is that foreign granite may be used instead of the quality of Scotch granite, as desired by the Paisley Town Council. In order, however, to have the points at issue settled, the Paisley Corporation have applied to the Board of Trade to appoint an arbiter.

Pontypridd.—At the ordinary monthly meeting of the District Council this week Mr. J. B. Hamilton was appointed to value the position of the tramway undertaking owned by the British Electric Traction Company between the town and Hafod, and the rolling-stock, loose plant, machinery, and furniture at Porth. Mr. Hamilton is the manager of the Leeds Corporation tramways. The committee recommended that double-decked cars should be used on the system, which, however, the engineer (Mr. R. P. Wilson) considered was impracticable owing to the bridges *en route* being too low to admit of their use. The clerk was, notwithstanding, instructed to reply to the engineer that the committee thought it desirable that such cars should be adopted, and to ask him to report further upon the matter.

Peak District.—A scheme is being prepared for the Light Railway Commissioners which affects this district. It is felt that Bradwell and Castleton should have better accommodation, hence the scheme for a light railway to both places. The plans, which have been prepared, show the new railway to commence at a point near the station at Hope, crossing the village of Brough, and proceeding to Grey Ditch. It then turns to the right, and crosses the Bradwell Brook and the road between the New Bath Hotel and the Bradwell Town End, where there is to be a station. From this point the line continues through the meadows to Castleton, where another station is intended, the entire distance being a little over three miles. The various landowners interested are giving the scheme their support. Electricity will be the motive power.

Tube Proposal for Woolwich.—The provision of adequate facilities for communication between North and South Woolwich has become acute. The free ferry boats cannot work in foggy weather, and great inconvenience and loss result. A local committee has been advocating a subway, but the proposal has thus far been shelved by the London County Council owing to financial considerations. The local committee has been informed that Sir John Szlumper has evolved a scheme which will get over the difficulty as far as pedestrian traffic is concerned. The proposal is to make a tube railway from the main Arsenal gates, running down Beresford-street, under the river, to North Woolwich. The details of the scheme are to be submitted by Sir J. Szlumper to the Bridges Committee of the London County Council at an interview they have granted him.

Bradford.—A dispute, which will probably be settled in the law courts, has arisen between the Bradford Corporation and the local authorities of Pudsey, Farsley, and Calverley, and relates to the rating of the Bradford tramways, which passes through those districts. The assessment has been made and has previously been paid by Bradford on the basis of a tramway. Bradford now contends, however, that the lines should be rated on the basis of a light railway. Light railways are classed as railways, and may under certain circumstances be entitled to an exemption of three-quarters of the district rate. The Councils, however, contend that the circumstances do not in this case justify an application of the law to this light railway, and that it is to all intents and purposes a tramway, and has been constructed by Bradford under the powers which they obtained in their local Act of 1899.

Portsmouth.—The financial results from the working of the tramways is furnishing a burning topic of local discussion. According to the auditors' report, a sum of £6,918, which appears as a balance at the end of two years' working, would not be there if a somewhat similar amount, which should have been debited to revenue, had not been charged to capital. The capital expenditure in the town stood at the end of March last at £620,000, of which £208,000 was the purchase price of the old company, leaving £412,000 as having been spent on depreciable property. Now, 5 per cent. on that amount means £20,600 per annum. The result of the two years' working, it is pointed out, is, therefore, a loss of upwards of £40,000 in the shape of depreciation not provided for, plus the normal maintenance, which will necessarily be an increasing item year by year. One of the local papers declares that to satisfactorily meet the position it appears necessary to earn nearly £30,000 per annum more than at present, without increasing the expenses—viz., £20,000 for renewals and £10,000 for current repairs and maintenance.

Leith.—A conference was held on Monday between the directors o the Edinburgh and District Tramways Company and a sub-committee of Leith Town Council, with regard to the proposals made by the Corporation for the working by the company of the Leith tramway system. Leith proposes on acquiring the tramways to introduce electric traction, doubling the lines where practicable, and to lease the whole to the company along with a portion of the depôt at Morton-place. They stipulate as a basis for negotiation that the lease should expire at the same time as that of the Edinburgh tramways, that the company pay them an annual percentage on the total cost of acquisition, conversion, and extension of the lines, and a rent for the other property, that they should take electric energy from the Corporation electric lighting station at 1½d. per unit, that fares and service be subject to arrangement, that the company take over the present horse plant at the cost to the Council, and that for the purpose of through traffic the lessees equip their electric cars so that these might be taken over the cable system to St. Andrew-square or other point agreed upon. The proposals were considered at the conference as a possible basis of agreement.

Metropolitan District Railway.—Messrs. Glyn, Mills, Currie, and Co., on behalf of the Metropolitan District Railway Company, invite subscriptions for £500,000 4 per cent. perpetual debenture stock. The prospectus states that the work of converting the District Railway from steam to electricity is steadily progressing, and that the engineers anticipate that the whole system will be equipped and ready for working by the end of next year. Provision is being made for a largely increased service of trains, and it is intended to provide eventually on the main line a service of 40 trains per hour, as against 18 trains now running, and on each of the five suburban western branch railways a 10 minutes' service. When the system is electrically equipped and in full working order, the company expects to carry at least 100,000,000 passengers per annum and to meet this it is providing a seating capacity for 143,548,000 persons per

Digitized by Google

annum. Part of the net proceeds of this issue will be applied for the general purposes of the company, and the balance will from time to time be paid over to the Underground Electric Railways Company of London, Limited, for the work of electrification. The subscription list opened yesterday, and will close on or before Saturday next at noon.

Sunderland District Electric Tramways.—The Sunderland District Electric Tramways, Limited, has been formed with a share capital of £270,000. The prospectus states that the company has been formed for the purpose of acquiring, constructing, and working certain tramways by electric traction through the colliery district in the neighbourhood of Sunderland, lying between the southern terminus of the Sunderland Corporation tramway system and the parish of Easington. A portion of the tramway is in course of construction. The tramways authorised comprise a length of 19¼ route miles, and will be of the standard gauge of 4ft. 8½in., being uniform with the Sunderland Corporation lines. The estimated population of the district to be served is 105,262, and besides traversing busy colliery centres, a considerable summer traffic to the seaside at Roker and other coast places in the neighbourhood is expected. The construction of the tramway, which has already been commenced, has been contracted for at the sum of £227,500, and it is anticipated that the line will be open for traffic next year. The purchase price for the provisional order and the benefits of contracts is £36,500, payable in cash. The Electric Conversion Syndicate, Limited, has agreed to guarantee the minimum share subscription of 150,000 shares for the sum of £12,500, payable as to £8,000 in cash and £4,500 in cash or fully paid shares, at the directors' option, and also a subscription of 600 debentures for a commission of 5 per cent. and a brokerage of 1 per cent.

Huddersfield.—At the last meeting of the Town Council the following report was presented: "The work of the tramways department has been steadily kept on during the past year. At the Longroyd Bridge power station the generating plant has been maintained, and continues to work satisfactorily. The rolling stock at present consists of 70 cars, comprising 22 bogie and 48 four-wheeled or truck cars. A contract has been entered into for the conversion of 12 of our bogie cars into truck cars, and this work is now proceeding, and is to be completed by Nov. 12, 1903. The cars have been kept in a thoroughly efficient state and in a clean condition. During the past municipal year the whole of our cars, with the exception of the bogie cars, have been fitted up with the Westinghouse-Newell magnetic brake. The work of equipping the bogie cars is now being carried out with all possible speed. This brake is a most powerful one, and its value has been fully demonstrated on two or three occasions, and what might otherwise have been a serious accident has been averted with the magnetic brake. The bogie cars have been fitted throughout with a new type of lifeguard—viz., the Hudson improved guard—the old kind of guard which we had on the bogie cars, known as the tray type, having been condemned by the Board of Trade. All the cars are now fitted with this very efficient guard, and, as in the case of the magnetic brake, it has fully proved its worth. During the year another addition has been made to a number of the cars by putting a cover over the top saloon. The total number of covered cars is 27. The present service of cars is 50 on ordinary days and 58 on Saturdays, as against 40 and 52 respectively the previous year. The overhead equipment and cables have been thoroughly maintained, and continue to give good results. The overhead work carried out by Messrs. Macartney, McElroy, and Co., Limited, has now been taken over by the Corporation. The total traffic receipts from Nov. 1, 1902, to Sept. 30, 1903, amount to £55,863. 17s. 6½d., being an increase of £9,006. 18s. 7½d. over the corresponding period last year. The total is made up as follows: receipts from passengers, £55,324. 13s. 3½d.; parcels, £496; miscellaneous, £43. 4s. 5d.—total, £55,863. 17s. 8½d. The mileage run during the period amounts to 1,410,768 miles, an increase over the corresponding period of 369,542 miles. The number of passengers carried is 10,353,213, an increase of 2,927,666 over the corresponding period."

Melbourne (Australia).—Through the courtesy of Mr. E. E. Rogers, who has charge of the Essendon and Flemington electric tramways lighting and power scheme, we are able to give some interesting particulars of the scheme, which has for its primary object the construction of electric tramways outside the city of Melbourne, Victoria, Australia. The Municipalities of Essendon, Flemington, Kensington, and Ascot Vale are situated together, immediately north of North Melbourne. The Melbourne tramways run cable cars to the northern boundary of North Melbourne. From this point it is proposed to construct two routes—first, through Ascot Vale, Kensington, and Flemington (all thickly populated), past the cattle yards, abattoirs, many of the principal warehouses, past principal entrance to Flemington Racecourse, Ascot Vale Racecourse, Royal Agricultural grounds, down to the Salt Water River, and on to the Moribyinong Racecourse. The line from the Salt Water River to the latter course is offered free of all cost of construction by the proprietor. The second route starts from the same point (North Melbourne terminus), and runs directly north through Ascot Vale and Essendon on past Moonee Ponds, Moonee Valley Racecourse, Queen's Park Gardens, to a terminus at the northern end of Essenden on the Mount Alexandra-road. The total routes to be constructed aggregate 7½ miles. The gauge is to be 7ft. 8½in. The promoters also have electric lighting and power rights at 6½d. and 4½d. per unit respectively. The resident population is 30,000, sufficient in itself to justify a tram and lighting scheme; but the extraordinary advantages in addition are that the system will have to carry passengers to the various places of amusement and sport the most popular around Melbourne. As an example of the attendance, the Royal Agricultural Show was held at the grounds recently. The attendance for three days was 52,000, 48,000, and 45,000 respectively. The attendance at Flemington on "cup" days often exceeds 100,000. Generally speaking, outside of the resident population of 30,000 for tramways and the electric lighting and power rights (in themselves a splendid concession), this little system for tramways will be fed by 500,000 people on "occasion" days alone. Mr. Rogers has had large experience in electric tramways, and as the late managing director of the Perth trams (which he put down and managed from their initiation till last month) he says he has never seen so good a proposition of its size as this. The concession is for 30 years. The straight-out fare is 2d. a ride, with the right to charge double on race-days and holidays.

London County Council.—At Tuesday's meeting of the London County Council, the Highways Committee had several reports on the agenda relating to tramways matters. In regard to the report presented to the last meeting recommending the Council not to purchase the London Southern Tramways Company's undertaking, and which was referred back, the committee now brought up a recommendation advising the summoning of a special meeting to decide the point. In the meantime, negotiations will be opened with the local authorities concerned with a view to seeing whether they will contribute to the cost of the street widenings involved in the reconstruction of the lines for electrical working. In another report the committee asked for authority to spend £1,500 for the purchase of tools, etc., in connection with the operation of the electric lines. The construction of the authorised tramways in St. John-street and Rosebery-avenue was the subject of another report, in which the committee recommended the adoption of the underground conduit system for these lines. The local authorities concerned are to be given an opportunity of expressing their views on the question. In regard to the payment of rent by the North Metropolitan Company in respect of the proposed new tramways, the committee recommended that an agreement be entered into with the North Metropolitan Tramways Company, providing (1) that the tramways, authorised by the London County Tramways Act, 1900, in St. John-street and St. John-street-road, shall, when constructed for the underground conduit system of electrical traction, be worked by the company by horse traction pending the reconstruction, for electrical traction, of the tramways with which they will be connected; (2) that during the period that the new tramways are worked by horse traction, the company shall pay to the Council a rent in respect of them equal to 8 per cent. per annum on the estimated cost—namely, £12,375—of their construction for horse traction, with the addition of £800 in respect of parliamentary, etc., expenses, making £13,175 in all; and, further, that when the new tramways shall be worked by electrical traction, the amount by which the actual cost of constructing the tramways exceeds the sum of £12,375 above mentioned shall, for the purposes of calculating the rent provided for in the company's lease, be taken as the cost of reconstruction for electrical traction. A joint report of the Highways and Improvements Committee was brought up recommending that the requisite powers be sought in the session of 1904 for the construction of a double line of tramways in the part of Wellhall-road proposed to be diverted and altered in accordance with the foregoing recommendation, such tramways to be in substitution for the proposed tramways between a point immediately south of the South-Eastern Railway and the junction of Woolwich-road and Eltham High-street, the construction of which was authorised by the London County Council (Tramways and Improvements) Act, 1902. Next week the Highways Committee will bring up a report, in which they state that in view of the proposal to proceed at an early date with the reconstruction for the conduit system of electrical traction of the first 22½ miles of the Council's (northern) tramways, steps should be at once taken to arrange for the supply of the rails and fastenings which will be required for this work. The Council authorised them to proceed with the preparation of the plans, etc., for the construction for an overhead system of electrical traction of the tramway in Archway-road authorised by the London County Council (Tramways and Improvements) Act, 1901, and rails will eventually be required for this purpose also. To ensure that there shall be no unnecessary delay in the carrying out of the works, they suggest that tenders should be invited for 12,500 tons of rails, conductor tees, fastenings, etc. This quantity of materials will suffice for the lines above referred to, and also for certain other works which, in their opinion, it is desirable should be put in hand at an early date, including the reconstruction of the present cable tramways between Kennington and Streatham. The cost of these materials is estimated at £90,000, and they propose that these shall be delivered and paid for as they are required. The prices for steelwork at the present time are very low, and they are advised that it is probable that the adoption of the course we suggest will result in a considerable saving, while the risk of delay will be obviated. They have sent to the Finance Committee the necessary estimate of £90,000, and recommend "that the estimate of £90,000, submitted by the Finance Committee, be approved; and that expenditure on capital account not exceeding that amount be authorised for the purchase of the rails, and other track materials, required in connection with the reconstruction, for electrical traction, of certain sections of the London County Council tramways and of the Council's (northern) tramways, and for the construction, for the same method of traction, of certain authorised tramways." The same committee will bring up another report next week with regard to the construction of new termini at Tooting. They will recommend "that the estimate of £13,850, submitted by the Finance Committee, be approved, and that the expenditure on capital account of sums not exceeding that amount in all, be authorised, in connection with the extension, under the powers conferred by the London County Council (Tramways and Improvements) Act, 1901, of the existing tramways in Tooting High-street, along portions of that thoroughfare and Defoe-road, and the construction of new termini in those thoroughfares." Mr. H. H. Asquith, K.C., has been appointed arbitrator with regard to the amount of rent to be paid to the Council by the North Metropolitan Tramways Company in respect of the new line of tramway constructed by the former in Agincourt-road, Hampstead.

Digitized by Google

LIGHTING AND GENERAL.

Derby.—The Electric Lighting Committee are purchasing property in Full-street.

Pontypridd.—The Council are raising a loan of £26,000 for electric lighting purposes.

Yeovil.—The Town Council have agreed to purchase a piece of land for electric lighting purposes.

Ramsgate.—Decision with regard to the electric light agreement has been deferred until Nov. 18.

Clitheroe.—The Corporation intend to apply to the Board of Trade for an electric lighting provisional order.

East Barnet.—Application is to be made for an extension of time for the carrying out of the electric lighting order.

London County Council.—Sanction was on Tuesday given to the borrowing by the Islington Borough Council of £3,753 for electricity meters.

Sowerby Bridge.—The Gas Committee have decided that now the gasworks are in good order to devote some attention to the electricity scheme.

Farnham.—In view of the applications before the Council as to electric lighting, the Board of Trade is to be asked to extend the order for another year.

Brynmawr.—The Urban District Council have decided to obtain the advice of an electrical engineer on the question of lighting the town by electricity.

East Ham.—The Urban District Council propose to apply for sanction to borrow £15,000 for extending the plant at the electric supply and tramways power station.

Stepney.—The Borough Council have decided to apply for sanction to borrow £2,845 for laying new distributing mains, and £1,670 for extension of public arc lighting.

Kirkcaldy.—In the Corporation's provisional order to be promoted next year powers are sought to enter into contracts for supplying electrical energy beyond the borough.

Agency.—The St. Helens Cable Company, Limited, have appointed Mr. James C. Boyd, of 33, Elm Park-avenue, Ranelagh, Dublin, as their representative for cables in Ireland.

Walton-le-Dale.—The Urban District Council intend to apply to the Board of Trade, on or before Dec. 21, for a provisional order under the Electric Lighting Acts, 1882 and 1888.

Chesham.—The Town Council have agreed to a proposal to pump the water at the waterworks by means of electric motors instead of the present gas-engines for one month as an experiment.

Newport (Mon.).—The Electricity Committee propose to supply power and light to a private firm at 1d. per unit, it being estimated that the firm indicated would need 250,000 units per annum.

Colne.—During the last quarter 12,665 units of electricity were sold against 6,136 last year. An increase of 100 per cent. is by no means discouraging for a new undertaking. The new plant is now all well in hand.

Eton.—At the last Urban District Council meeting the vice-chairman said he did not think the cost of electrical power at the pumping station exceeded the price of the coal bill for the previous six months.

Monmouth.—An extra cable is to be purchased, at a cost of £250, to be laid between the generating station and the North-parade, in case the existing cable should fail, and to meet the increasing demand for the light.

Northumberland.—At the quarterly meeting of the County Council it was reported that the work connected with the installation of the electric light at the county asylum, at a cost of £8,496. 6s. 3d., had been completed.

Calne.—The Town Council have resolved to apply for a provisional order to supply electricity for all public and private purposes within the borough and the parishes of Langley Burrell, Chippenham Without, and Hardenhuish.

Sherburn.—A deputation of the Parish Council will seek an interview with Mr. Hornsby to enquire whether and upon what terms the Lambton Colliery Company can supply the parish with public electric lighting, and report to the Council.

Newcastle.—The Finance Committee have arranged that a deputation wait on the Tramways Committee respecting the price levied for the electric lighting of public buildings. The committee were of opinion that the price ought to be reduced.

Dunfermline.—The National Electric Construction Company, London, intend to apply for a provisional order granting to them statutory powers in the burgh. The Fife Electric Supply Company propose to lay down a station at Cowdenbeath.

Cookham.—The Rural District Council have decided to consent to the application of the Maidenhead Town Council for a provisional order authoriting the supply of electricity for public and private purposes within the parishes of Cookham and Bray.

Clacton.—The Urban District Council have received sanction to the application to borrow £15,225 for the purposes of electric lighting. A deputation will wait on the Board of Trade with a view to obtaining a further extension of the time granted by the order.

Sale of Plant.—An auction sale of an extensive stock of electrical lighting plant, dynamos, machinery, and surplus stock of accessories will take place by Messrs. Terson and Son, London-road, Buckland, Dover, on Nov. 24 to 26. Particulars appear in another column.

Banbury.—We understand that the Town Council have accepted an offer of the Banbury and District Electric Supply Company, Limited, to place two arc lamps in positions to be approved of, and at the expense of the company, for the purpose of demonstrating the use of the light for public lighting.

Manchester.—The Corporation will promote a Bill containing clauses to authorise them to supply electrical energy beyond the city and to acquire land and execute works in connection therewith. This has become necessary because of the agreement made with the Southern Tramways Company, whereby the Corporation would work the tramways towards Altrincham.

South Africa.—We are informed that the directors of the Cape Town Industrial Exhibition (International) are open to receive offers for lighting the grounds, etc. This exhibition opens in November, 1904, and closes at the end of January, 1905. The Belgian Government have decided to take part officially, and will expend £40,000 for the purpose. The address of the managers is Palmerston House, Old Broad-street, London, E.C.

Hull.—Last week we referred to a local agitation for a reduction in the price of current. It appears that the Corporation Committee, who have already agreed to make a uniform charge for meters, are of opinion that no reduction in the price of current can be made until the end of the financial year, which closes on March 31. During the half-year ending Sept. 30 there has been an increase of 60,156 units used for motors, and the revenue from the sale of current has increased from £9,144 to £11,877.

Flax Spinning.—We understand that the Irish Flax Spinning Company, of Belfast, have placed a contract with the British Thomson-Houston Company for the electrical operation of the extensions to their mills now in course of erection. The contract comprises the provision of a 60-kw. three-phase generator, switchboard, and three motors for driving the various rooms in the mill, which contain the usual flax-preparing and spinning machines. It will be interesting to watch the development of this, which we believe to be the pioneer scheme of electrical operation of flax machinery in Ireland.

Stock Exchange.—The Stock Exchange Committee have appointed Nov. 11 a special settling day for Charing Cross and Strand Electricity Supply Corporation's 4,000 "City Undertaking" 4½ per cent. cumulative preference shares (1903) of £5 each fully paid, Nos. 40,001 to 80,000; and London United Tramways (1901), Limited, further issue of £206,000 4 per cent. first mortgage debenture stock, and have ordered the said securities to be quoted in the official list. Application has been made to the committee to appoint a special settling day in and to grant a quotation to Dick, Kerr, and Co.'s 52,000 ordinary shares of £5 each fully paid, Nos. 1 to 52,000, 61,000 6 per cent. cumulative preference shares of £5 each fully paid, Nos. 1 to 61,000, and £300,000 4½ per cent. debenture stock.

Ammonia Sulphates.—Mr. Walker Smith, the borough surveyor of Barrow, has been lecturing to the townspeople on the municipal undertakings. In the course of his lecture, Mr. Smith referred to the refuse destructor, and spoke of the possibility of extracting nitrogen from the refuse as ammonia, which could be sold at about £12 per ton as ammonia sulphates. He also alluded to the fact that the steam could be used for generating electricity for the tramways, and they expected to obtain 1¼lb. of steam from 1lb. of refuse. Thirty per cent. of the residual clinker would be used for roadmaking, and it could also be crushed for filtering material or ground for flags, etc. But the greatest real profit of all would, he said, be the sanitary reform which was effected. The amount of refuse burned daily would be 40 tons.

Swansea.—The electrical engineer, Mr. Prussman, is drawing up specifications for the high-tension plant for lighting Morriston. A number of Nernst lamps are also to be installed. The members of the Corporation Electric Lighting Committee, with a number of friends, paid a visit of inspection to the Corporation electric lighting station, Strand, on Friday evening, where a change-over was effected from one of the largest engines to the other in 1min. 40sec., and Mr. Prussman, engineer, explained that that was the longest time the town would be in darkness through failure of an engine at any time. Notwithstanding a hitch in the original arrangement for the construction of an electric organ in St. Mary's Parish Church, Swansea, the committee of the church have determined to realise their scheme, and they have just decided to arrange with Messrs. Norman and Beard, of Norwich, who are constructing a similar instrument for the new Roman Catholic cathedral at Westminster, for an instrument to cost £3,000, and be the finest of its kind in South Wales. The work will be proceeded with in two sections, and the first will be opened by Easter. The organ will be blown by electricity from the Corporation mains.

Frome.—A curious bargain has been struck by the Urban District Council with Messrs. Edmundson's Electricity Corporation, Limited, the holders of the electric lighting order. The Council have decided to allow the company the use of the waste water from the baths during seven months of the year, and charge them for water supplied during the remainder of the period from the mains at 1d per 1,000 gallons. An agreement is to be prepared embodying this arrangement, and containing a clause that if at any time during the continuance of the arrangement it should be found that owing to the increased cost in fuel, or wages, or other expenditure the water could not be lifted to the reservoir at less than 1d. per 1,000 gallons, the charge should be proportionately increased for the time being. In consideration of the Council having done so, the company have decided to treat the lighting of all premises owned by the Council as "public lighting" and supply current for lighting such premises at a flat rate of 2½d. per unit. They will also supply current for power purposes to the Council at a reduction of 10 per cent. on their standard rate or at a flat rate of 1½d. per unit, at the option of the Council. Complaint is made that the Council which charges other consumers 6d. per 1,000 gallons is giving the water away, but it was explained that it was not desired to overload Messrs. Edmundson's with expense, as the Council was providing the necessary capital, and hoped to purchase the company's interests within seven or ten years.

Digitized by Google

Steyning.—The Brighton Corporation have asked the Council to consent to terms for the supplying of electricity to certain villages in the district, but as there is no evidence of any desire for electricity in the parishes named no action has been taken in the matter.

Arc Lighting in the Suburbs.—With reference to the article "Gilbert Arcs in North-West London," in our last issue, we are informed that the very graceful columns both for Willesden and Hampstead were supplied by Messrs. Rowland Carr and Co., Lime-street-square, E.C.

London School Board.—The Board propose to expend £398 for supplying installation and fittings required for the electric lighting of the Gravel-lane School, Houndsditch. The work is to be executed by workmen employed direct by the Board, under the instructions of the architect of the Board.

Burgess Hill.—The Brighton Town Council have informed the Council of their intention forthwith to proceed with the construction of their telephone system within the district, and they have received permission to erect black fir telephone poles as they proposed in the roads within the district.

Glastonbury.—The Telephone Sub-Committee have circularised the town for subscribers to the proposed telephone service, but only received 38 replies, comprising nine promises of intention to subscribe and 29 refusals. The result is to be sent to the Wells Town Council, who instituted the idea.

Margam.—The proposal for a joint electric lighting and traction scheme for Port Talbot and Aberavon has been defeated by five votes to four. The chief argument of the opposition was that an electric tramway between Taibach and Aberavon would draw people into Aberavon and be detrimental to the trade of Taibach.

Louth.—The Town Council have accepted the proposal of the Sir Hiram Maxim Company, who had expressed their readiness to purchase the rights of the Council under the provisional order, and to supply electricity at an average of not more than 6d. per unit for private lights, 4d. per unit for public lighting, and 3d. per unit for motive power.

Longton.—The Corporation have sanctioned the extension of the electric cables to the British Anchor Pottery and to Beaconsfield Works, both in Anchor-road. Both firms have given a guarantee of a consumption equal to 10 per cent. upon the expense, and the work will be proceeded with at once. Messrs. Callender and Co. are the contractors.

Sleaford.—Mr. R. S. Yates, the electrical engineer, in his last report, states that in 1901, for four weeks, 582 units were generated, there were 21 consumers, and 253 lamps connected, the cost per unit being 3⅞d. In the corresponding four weeks in 1903 2,860 units were generated, 97 consumers, 1,988 lamps connected. The cost per unit of production had been reduced from 3⅛d. to 2⅝d.

Whitby.—The Urban District Council have decided to apply for sanction to the raising of a further loan of £2,000 for the purpose of laying a feeder from the central station to the end of Argyle-road, and for the further extension of cables, with the idea of lighting the whole of the public lamps with electricity. Mr. L. H. King, resident engineer to the Council, has been appointed consulting electrical engineer.

Bury St. Edmunds.—The report of the electrical engineer (Mr. L. P. Greig) mentions that during October five new services, equal to 104 8-c.p. lamps, and a motor of 1½ b.h.p. had been applied for, showing the steady advance made by the department was being maintained. The comparative statistics show the results of the past year's work to be most satisfactory. The total income to April 1, 1903, amounted to £2,251, as compared with £1,194 to April 1, 1902.

Wolverhampton.—The Lighting Committee propose to provide at the electricity works, Commercial-road, further engineering plant at a cost of £1,200, and also to erect a coal-conveying plant at a cost of £850. The latter will dispense with a great deal of labour in unloading boats and the use of wheelbarrows to the furnaces. The consumption of fuel is over 10,000 tons per year, and the proposal will effect a saving in its removal from canal boats to the steam-boilers.

Whitchurch.—At Tuesday's meeting accounts amounting to £637 were passed, and Mr. Martin explained that this included £150 for the telephone extension to the waterworks. The clerk reported that he had not yet received the requisite number of signatures required by the Post Office authorities for the establishment of the telephone communication in Whitchurch, but as there were only 25 guarantors required he hoped this number would soon be forthcoming.

Cab Calls.—The National Telephone Company propose, if a sufficient number of subscribers can be obtained in a district, to make telephonic communication with the nearest cab shelter, so that cabs can be called to private residences, thus doing away with the baleful whistle which often disturbs a whole neighbourhood. The subscription will be very moderate, and should benefit both householders and cabdrivers. The first experiment is to be made at Portland-place.

Arnside.—In answer to a requisition signed by several ratepayers of Arnside, and presented to the Parish Council, a meeting of ratepayers was held on Monday to discuss and determine whether the provisions in the Lighting and Watching Act, 1833, relating to lighting should be adopted and carried into execution in this parish. In the end a committee was appointed to consider various schemes for lighting the village and ascertain the approximate cost, and to present their report at a further meeting.

Bognor.—A letter having been received last week from the National Provincial Electricity Corporation, Limited, enquiring whether the Council would support their application for a provisional order empowering them to supply electricity in the Council's district, the latter decided to reply that they were already entering into an agreement for the supply of electric light to the town under their provisional order, and that under the circumstances they were not prepared to enter into negotiations with them.

Gelligaer.—At the District Council meeting last week Mr. A. Hayter dealt with the lethargy of the District Council in not providing proper light for the district or adopting some measures to bring about a reform. He suggested that they should ask the South Wales Electrical Power Company to send down a man to lecture upon the efficacy of electric light over gas. If they could not get works in Bargoed, they might be able to arrange with the Powell Duffryn Company to run a cable over, as was done at Bedwellty Pits.

Carnarvon.—The National Electric Contruction Company have declined to consider the proposal whereby they should undertake the distribution work in the borough immediately, and put down a temporary generating plant for use until the North Wales Power Company were in a position to supply in bulk from Leydaw Lake. They are, however, agreeable to putting down temporary plant to supply current until their Leydaw station was ready. An expert has been engaged to advise on the respective merits of the schemes.

St. Marylebone.—The Council have received a report from a sub-committee on the question of the cost of lighting the underground public conveniences. It was found that in many cases 8-c.p. lamps would give an efficient illumination where at the present time 16-c.p. lamps were in use, and the substitution of 33 8-c.p. lamps in place of 33 16-c.p. lamps has been arranged for. At an expenditure of £3, the lights over the w.c.'s would be utilised to more advantage by having shade carriers with shades, so as to throw the maximum candle-power of the lights downwards instead of on to the ceiling. It was also arranged to fix such contrivances.

Electrical Exhibition.—The Corporation of Eastbourne propose to hold an electrical exhibition at the town hall from Tuesday, Dec. 2, to Saturday, Dec. 6, inclusive. We understand that the committee will welcome novelties in the way of electric lighting or decorative effects, heating, cooking, ventilating apparatus, and electric power-driven machinery, or any other apparatus, fittings, or accessories relating thereto which might be of interest. A supply of electrical energy can be obtained at 200 volts alternating current and a frequency of 50, the rate of charge being 2½d. per unit for all purposes. A minimum fee of £1 will be charged in order to partially cover the cost of the service.

Plymouth.—Subsequent to the withdrawal of their recent Bill from Parliament, the Corporation applied for sanction to borrow the sum of £248,252 for purposes of electric lighting, sewerage, street improvements, parks, workmen's dwellings, and other works. Of this sum about £170,000 was in respect of capital expenditure already incurred, and the balance of nearly £80,000 represented further capital expenditure to which they are committed during the current financial year. In addition, the Council also applied for sanction to borrow £3,200 for repaving Sutton-road, and £6,700 for electric lighting purposes. Mr. E. Pearse Burd and Mr. H. Percy Boulnois, C.E., will hold an enquiry next Tuesday.

King's Lynn.—The electrical engineer in his last report states that applications had been received for 511 additional lamps of 8 c.p. or equivalent, making a total of 16,953 from private consumers. The total number of consumers up to date was 434. One motor of 8 h.p. had been ordered during the past month. The units sold to private consumers for the first six months of the present financial year, as compared with the same period last year, showed an increase of 30 per cent. for light and 178 per cent. for power. The output for power was greater than the output during the whole of last year. The working expenses for the six months were practically the same as those of the same period last year.

Ayr.—The following figures appear in the last report of the borough electrical engineer, Mr. Roland Marshall: "Number of consumers as per last report, 721; number connected during month, 3—total, 724; number of lamps connected as per last report, 28,041; number connected during month, 260—total, 28,301; number of motors connected as per last report, 13; number connected during month, 2—total, 15; units generated as per last report, 340,302; generated during month, 115,076—total, 455,378; generated for corresponding period last year, 436,491—increase, 18,887. The Blackburn-road new sub-station has been erected during the month, and is now ready for the cables, which I hope to get laid next week. The work of heightening the chimney has been commenced."

Lowestoft.—The engineer has been instructed to lay a network for 50 yards on the east side of Corton-road to supply new houses. There are now 433 consumers connected to the mains, representing 29,975 8-c.p. lamps; there was an equivalent of 64 8-c.p. lamps connected to the mains during last month. The tramways are paying an average of £45 or £46 per week for current. The matter of free wiring was considered, but after considering the various offers, it was agreed that the matter be not entertained for the present. It is proposed that all consumers are to be given the option of taking the current either on the present maximum demand system of 7d. and 3d., or at a flat rate of 6d. per unit, on signing an agreement to take the current for twelve months on the system selected.

East Dereham.—The Urban District Council last week considered a communication from the Southern District Electricity Corporation, who some time ago wrote to the Council stating that they intended to apply to the Board of Trade for a provisional order for supplying the town with electricity, and they now submitted terms upon which they proposed to deal with the matter, and asked the consent of the Council to their application. They would find all the capital for constructing and running the works, but in order that the residents of the neighbourhood who might desire to become interested in the undertaking might have an opportunity of subscribing for shares, they would form a local company, and give preference in allotment to applications of residents. They also submitted the terms they would be prepared to charge for lighting and power, and stated that the Council would have the right to purchase the undertaking at any time during the period of the order by giving one year's notice.

Digitized by Google

Hampton Wick.—At the last Council meeting a letter was read from the Twickenham and Teddington Electric Supply Company enclosing draft copy of their provisional order, and asking the Council for their formal consent. They were prepared to give the Council the right to purchase the undertaking at a valuation as a going concern at the end of seven, fourteen, or twenty-one years, and to supply electricity to private consumers at the following rates: 7d. per unit for the first hour per day at the maximum demand, or its equivalent, and 3d. per unit for any further quantity. As it could not be a clause in the order, they would be prepared to enter into an agreement to supply electricity for public lighting at a price not exceeding 2½d. per unit. The clerk was empowered to obtain an independent report on the proposal, and the subject was therefore adjourned for further consideration.

Bridgend.—The arrangement of the District Council with the Electrical Power Company states that in consideration of the permission of the Council being granted to the company to supply customers with energy for power and light, the company will not charge the ½d. for transforming, and the company undertake to pay to the Council 2½ per cent. on the gross estimated sum receivable from all future customers for energy for both light and power. This arrangement is for 12 months only, and is then to be determined or made permanent at the option of the Council, and not at the option of the company. The company further undertakes not to encourage the supply of power to private individuals or firms, and if any dispute arises out of this new arrangement as to whether any person or firm is one to whom power and not lighting is the chief consideration, the question shall be decided by an outsider nominated by the chairman of the Council and chairman of the company.

The New Pacific Cable.—Some interesting figures have been compiled, says the Central News, showing the expenses and receipts of the new Pacific Cable. The cable was opened early in December last, and consequently three months' revenue is all that can be set off against 2¼ years' expenditure—that is, from the initiation of the business. The expenditure during that period up to March, 1903, was £120,000, and the revenue for the three months ended March this year was £18,310, showing a deficiency of £101,690. This deficiency will have to be made good by the parties to the scheme as follows: United Kingdom and Canada, £28,055 each; Victoria, New South Wales, Queensland, and New Zealand, £11,222 each. The estimated expenditure for the next financial year is £165,500, and the receipts £75,400, which will leave an estimated deficiency of £92,100. This loss will be apportioned among the Governments concerned as follows: United Kingdom and Canada £25,409; Victoria, New South Wales, Queensland, and New Zealand, £10,072 each. Australia bears one-third of the annual charge.

London Gazette.—The partnership existing between William Townend Drabble, Samuel Carter, and Thomas Carter, in the trade or business of electrical engineers, carried on at West-street, Leeds, under the style of Drabble, Carter, and Co., was dissolved on Aug. 24, 1903. All debts due to and owing by the late firm will be received and paid by William Townend Drabble, by whom the business will in future be carried on. A dividend is to be declared in the estate of John Frederick Worthington, electrical engineer (trading with Gerald Nuttall under the style of Worthington and Co.), Foundry Works, Foundry-street, Hanley, Stafford. Last day for receiving proofs, Nov. 21, at the office of Messrs. Poppleton and Appleby, 26, Corporation-street, Birmingham. A petition for the winding-up of the Electrical Publishing Company by the High Court of Justice, presented by Thomas William Sheffield, of Trevellyan-buildings, Corporation-street, Manchester, is to be heard before the Court sitting at the Royal Courts of Justice, Strand, London, on Nov. 24, 1903. The Light Railway Commissioners have submitted to the Board of Trade for confirmation an order made by them amending the Robertsbridge and Pevensey Light Railway Order, 1900. Any objections to the confirmation of the order should be sent to the Assistant Secretary (Railway Department), Board of Trade, Whitehall-gardens, London, S.W., on or before Nov. 28, 1903. Copies of the order may be obtained from Messrs. Cheesman and Cope, 15, Victoria-street, Westminster, S.W., and 23, Havelock-road, Hastings.

Hove.—The Town Council have sanctioned the application of the National Telephone Company for permission to lay underground ducts within the borough, subject to the following conditions: The routes to be approved by the Council, and the Western-road to be excepted; the Council to be at liberty to grant a similar concession to any other authority; the Council to construct the ducts, the company finding the funds for that purpose and for keeping the ducts in repair; the ducts to be the property of the Council, the company to have license to use the same until May 1, 1926; the license to use the ducts shall not be transferred or sublet without the consent of the Council, excepting that if the Postmaster-General exercises his power to purchase the undertaking of the Telephone Company, they shall be at liberty to sell their interest in the license to him, subject to the obligations and liabilities affecting the same; an annual payment of 5s. to be made to the Corporation for each subscriber in Hove above the £5. 10s. charge, and 2s. 6d. each subscriber at or below that charge; in the case of party lines the annual payment to be 1s. 3d. each subscriber; in the event of the company increasing or abolishing the present scale of charges for telephone service in the borough, then the charge to telephone subscribers for unlimited service shall not at any time thereafter exceed £8 per annum; in the event of the company reducing the present charges for unlimited service to subscribers in any city or borough with a population according to the then preceding census of 150,000 and upwards (excluding the Metropolis) below those in operation in the borough of Hove, the company will reduce the charges to subscribers within the borough of Hove to similar amounts; the whole of the borough to be considered as within the "two-mile radius"; the company to pay to the Council half the cost of laying the existing ducts in Church-road, their right of user being limited to three channels; a formal agreement embodying these terms and such further details as the Council may be advised to be entered into, and until such agreement is completed, the Council not to be bound; that cost of the agreement to be paid by the company.

PROVISIONAL PATENTS, 1903.

Nov. 2.

23686. An improved fog or danger signal for steam or electric railways. Arthur Johnson, The Highlands, Broomy-hill, Hereford.

23712. Improvements in the manufacturing of dry batteries. Henry Nehmer, 36, Clifton-street, Finsbury-square, London.

23715. Improved apparatus for operating railway signals and points by electricity. Edmond Meyer Tudor Boddam, 71, Bishopsgate-street, London.

23716. Improved electric interlocking apparatus for operating electrically worked signals and points. Edmond Meyer Tudor Boddam, 71, Bishopsgate-street, London.

23717. Improved method of operating electrically worked signals by means of contacts made by moving trains. Edmond Meyer Tudor Boddam, 71, Bishopsgate-street, London.

23743. Improvements in electrical indicators. Leopold Percy Coppard Hodson, 55, Chancery-lane, London.

23750. Improvements in or relating to electric signalling apparatus for railways. Edouard Danneels, 72, Cannon-street, London. (Complete specification.)

23767. Improvements in galvanic batteries. The Halsey Electric Generator Company, Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (The Halsey Electric Generator Company, United States.)

Nov. 3.

23830. Improvements in or relating to electric light and similar fittings. William Wickstead Barton, 111, Hatton-garden, London.

23833. Improvements in electrical resistances. Percy Macaulay Ashworth Matthews, 9, Teneriffe-street, Lower Broughton, Manchester.

23851. Improvements in electric cranes. Stothert and Pitt, Limited, and Walter Pitt, 24, Southampton-buildings, Chancery-lane, London.

23853. Mercury electrolytic apparatus specially applicable to electric meters and electric switches. Edward Du Bois and the Reason Manufacturing Company, Limited, Norfolk House, Norfolk-street, Strand, London.

23854. Method of effecting a phase-shift of 90deg. or more between the pressure and the field in the shunt circuit of alternating-current meters. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckert Werke G. m. b. H., Germany.) (Complete specification.)

23862. Improvements in electric log recording and like apparatus. Hjalmar von Kohler, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

23863. Improvements relating to electric distribution systems. Josef Henrik Hallberg, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

23876. Improvements in or relating to autographic telegraph systems. Arthur Korn, 18, Buckingham-street, Strand, London. (Complete specification.)

Nov. 4.

23915. Electric light adaptor for reading lamps. Walker Laird Miller, 222, Berkley-street, Glasgow.

23928. Improved means applicable for use in automatically cutting out resistance in alternating-current electro-motors. John Bush, 90, Lausanne-road, Peckham, London.

23933. Improvements in shades or reflectors for electric and other lamps. John Laird, 9, Warwick-court, Gray's Inn, London.

23948. Improvements in and connected with electric tram-cars. George John Conaty, 128, Colmore-row, Birmingham.

23956. Improvements in connection with vacuum brake apparatus for electrical and other railways. James Gresham and Henry Albert Hoy, 18, Southampton-buildings, Chancery-lane, London.

23961. Improvements in meters for use in connection with electric heating systems, and other systems or apparatus consuming energy, or for recording periods of time. Edward Cunliffe-Owen, Edward William Johnston Macdonald, and A. F. Harmer, 322, High Holborn, London.

23978. Improvements in and relating to overhead electric current conductors. Emile Giraud, 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, Nov. 5, 1902, being date of application in France.) (Complete specification.)

Nov. 5.

23987. Improved electric ignition devices for gas-engines, oil-engines, and petroleum motors. Elias de la Roche Rendell and George Arthur Minshall, Longport, Stoke-on-Trent.

Digitized by Google

23988. Improvements in the means for electrically operating switches and other apparatus. Henry James Fuller, 13, Park-view, Beeston-hill, Leeds.

24013. Improvements in or connected with electric light switches. James Walter Thompson, 71, Albion-street, Leeds.

24023. Improvements in or relating to electric arc lamps or mercury vapour lamps or the like. Charles Orme Bastian, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

24025. Improvements in printing telegraph receivers. James Dundas White, 50, Clanricarde-gardens, London.

24055. Improvements in apparatus applicable for use in connection with telephones and other purposes. John Alexander Gamble, 6, Lord-street, Liverpool.

24070. Improvements in storage batteries. Franklin Wise Howorth, 46, Lincoln's-inn-fields, London. (David P. Perry, United States.)

Nov. 6.

24083. Improvements in electrical apparatus used in propelling autocars and other vehicles, launches, and the like. Edmund Scott Gustave Rees, Prince's-chambers, Wolverhampton.

24098. An apparatus for limiting electric currents. José Azarola, 4, Corporation-street, Manchester. (Complete specification).

24102. Improvements relating to electric ignition apparatus for motor cars, motor cycles, and the like. William Walter Gerald Webb, John Hall, Charles Herbert Offord, and Archibald Carlyle Barfield, 18, Southampton-buildings, Chancery-lane, London.

24116. Improvements in electrical machines. Bernard Charles Molloy, 5, Paper-buildings, The Temple, London.

24127. Improvements in electric bath tubs and in electrodes therefor. Josef Zwiebel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24129. Improvements in the structure of alternators. Arnaldo Paulo Zani, 18, Southampton-buildings, Chancery-lane, London.

24142. Improvements in regulating means for electric lamps. Howard Coppuck Levis, 83, Cannon-street, London. (Albert Gould Davies, United States.)

24144. Improvements in electrically controlled valves. Oscar Junggren, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Nov. 15, 1902, being date of application in United States.) (Complete specification.)

Nov. 7.

24200. A portable electric fan. Max Margowski, 72, Cannon-street, London. (Rudolf Klemm, Germany.)

24212. New or improved means for controlling arc lamps. Herbert John Haddan, 18, Buckingham-street, Strand, London. (The firm trading as Samuel Zielenziger, Germany.) (Complete specification.)

24214. Improvements in and relating to attaching devices or connections, especially applicable to electric fuses. William Richard Macdonald and George Edward Heyl-Dia, 322, High Holborn, London.

24216. Improvements in cut-outs having two or more fuses. Thomas Herbert Marsh and Henry Herbert Stanley Marsh, 322, High Holborn, London.

24217. Improvements in and relating to automatic fuse cut-outs and cut-ins. Thomas Herbert Marsh and Henry Herbert Stanley Marsh, 322, High Holborn, London.

24220. Improvements in apparatus for lighting gas lamps by electricity. Otto Gergacsevics, 6, Lord-street, Liverpool.

24223. A device constituting a combination of an electric lamp with a lighter for cigars and the like. John Edward Waller, 47, Lincoln's-inn-fields, London.

24235. Improvements in electric arc lamps. William James Davy, 40, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Nov. 26, 1903.

1902.

24148. Electric fuses. Esson.

24149. Electric fuses. Esson.

24192. Trolley collectors employed in overhead systems of electrical traction. Rowlands.

24295. Switch lampholders for incandescent electric lamps and the like. Hewett.

24235. Heating by means of electricity. Bronn.

24328. Electric incandescent lamps. Bowen.

24517. Method of constructing electric resistances for heating or other purposes. Hankin.

24576. Telephone party-line system on telephone exchanges working on central battery system. Oppenheimer. (Actiengesellschaft Mix und Genest.)

24643. Detection of faults in the conductors of electric traction systems. De Ferranti.

26051. Trolley poles for electric railways. Carolan. (General Electric Company.)

24709. Electric cut-outs. Carolan. (General Electric Company.)

27619. Control of electromotors on electric railway cars. Siemens Bros. and Co., Limited, Lydall, and Duke.

27761. Electric cut-outs. Carolan. (General Electric Company.)

27772. Electric regulators. Carolan. (General Electric Company.)

27858. Electric light switches and the like. Eckstein and Krause.)

28384. Automatic minimum and reverse current circuit breakers. Thomas and Thomas.

28486. Electric switches. Leitner and Lucas.

28487. Means for controlling variable-speed dynamos. Leitner and Lucas.

28552. Conductors or oscillators for use in electrical wireless telegraphy. Lake. (Stone.)

1903.

3426. Chemical rectifiers for converting an alternating electric current into a direct current. Chaplin.

7831. Process for manufacturing electrodes for arc lamps. Hopfelt.

11427. Radiator systems for wireless telegraphy. Blondel. (Date applied for under International Convention, May 28, 1902.)

16487. Telegraph pole. Schütz.

21304. Driving electrical machines by means of steam-turbines. Siemens Bros. and Co., Limited. (Siemens und Halske Actiengesellschaft.)

22639. Covers and frames for electric junction boxes and the like. Robinson.

THE SPEED REGULATION OF THREE-PHASE MOTORS.*

There are three principal methods of regulating three-phase motors: (1) by changing the number of poles; (2)

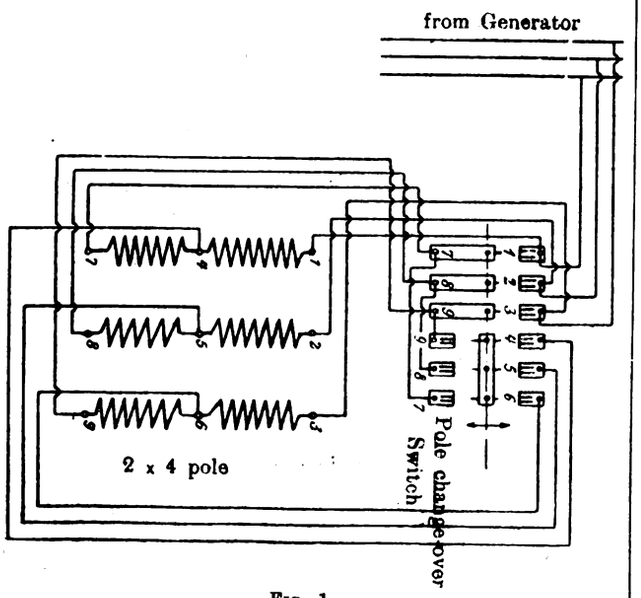

FIG. 1.

by inserting resistances in the rotor; (3) by employing a number of motors arranged coaxially and wound with different numbers of poles.

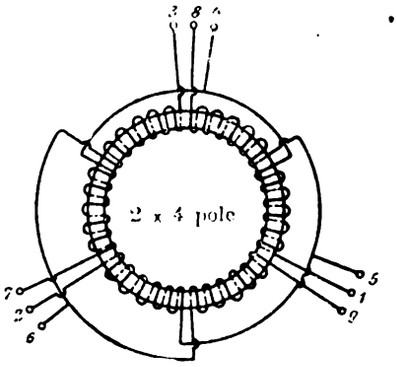

FIG. 2.

Each of these methods may be carried out in various ways. The earliest three-phase motors had Gramme-wound stators, and for these a simple switch is all that is necessary to change the poles in the ratio of 1 : 2. The connections for this purpose are shown in Figs. 1 and 2 for a two to four pole arrangement. The writer recently constructed a 3-h.p. motor of this type having a stator of 190mm. internal diameter and 355mm. external diameter, and a core length of 70mm. It was designed for 415 volts at 50 periods. The stator had 48 slots with 32 conductors in each, and the rotor had a four-pole short-circuited winding, with two bars in each of the 72 slots. The starting torque of such a motor is almost nil with the four-pole coupling. This

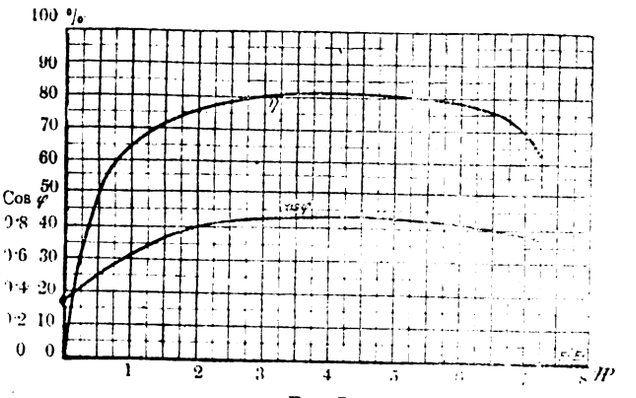

FIG. 3.

machine required 28 amperes at 410 volts in order to start light, and took eight seconds to attain full speed. With the two-pole coupling, on the other hand, the starting torque is very good, the maximum torque obtained being equivalent to 6 h.p., and the current taken being 28 amperes at 400 volts. It is characteristic of all motors arranged for pole changing that a lower starting torque, output,

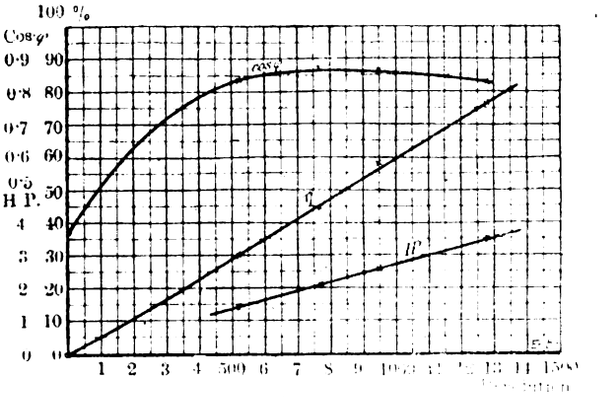

FIG. 4.

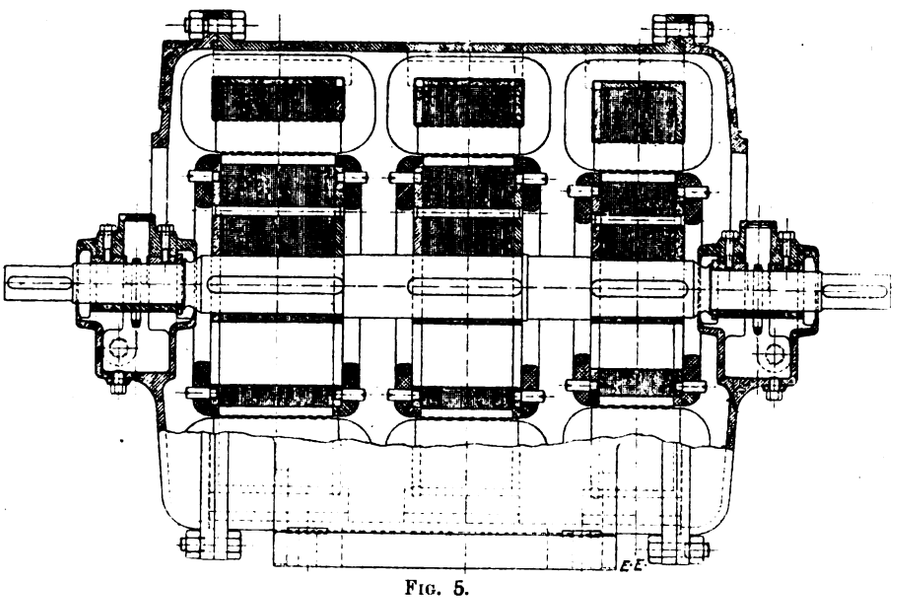

FIG. 5.

efficiency, and power factor are obtained with the low than with the high speed coupling. On this account such motors have to be started with the high-speed connections when

* Translation in abstract of an article by W. Burkard in *Elektrotechnische Zeitschrift* for Aug. 27, 1903.

Digitized by Google

any considerable starting torque is required, as for cranes or machine tools, and this is unsatisfactory, on account of the sudden shock to the machinery leading to such excessive currents as to often melt out the solder of the rotor con-

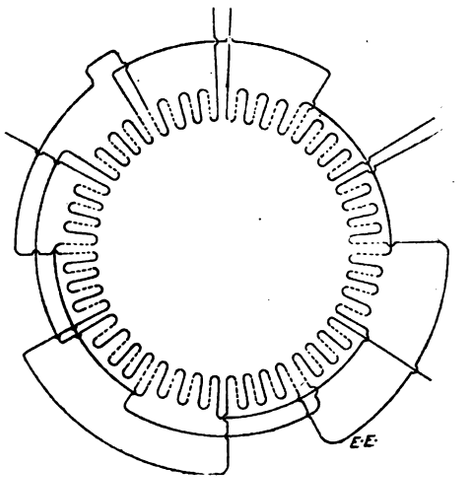

FIG. 6.

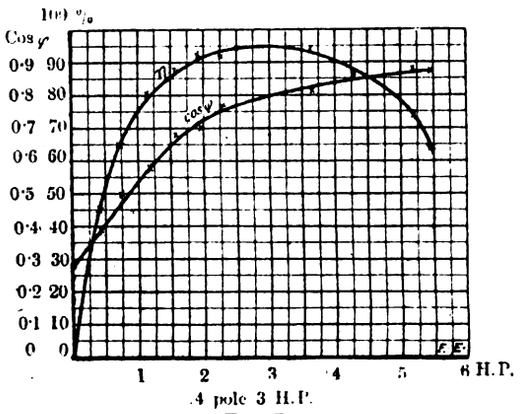
nections. When drum wound motors came into use, various modifications were patented to permit of coupling up to suit different numbers of poles, but all suffer more or less from the same disadvantages as the Gramme windings.

though the carbon brushes glowed in this case, due to the excessive currents passing.

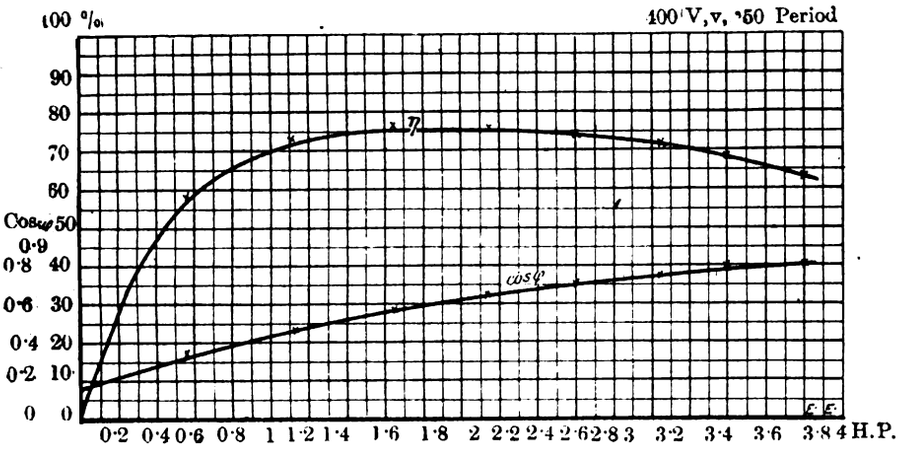
The third method of speed regulation, by means of several motors mounted on the same shaft, was first employed in 1901 by Messrs. Wüst and Co. All the different elements of such a motor may be wound for the same load, but each for a different number of poles; or, as



4 pole 3 H.P.

FIG. 7.

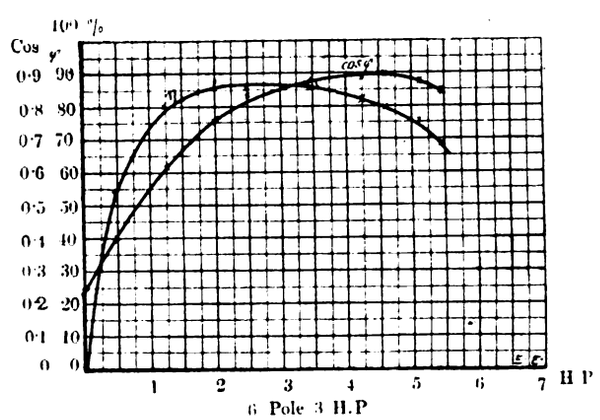
is sometimes preferable, the higher speed elements may be designed for more power than the lower speed ones. The lowest speed element can, if desired, be wound for a very large starting torque. Should it be necessary to obtain a considerable overload for a short time, as in the case of a steep gradient on a railway line or an excessive load on a crane, all the elements wound for different poles can be coupled in parallel, and in this way an output can be obtained which is at least as great as the sum of the powers of all the elements at a given speed (which is smaller than that corresponding to the largest number of poles). Fig. 5 shows a three-step motor of this type having three elements of 3 h.p. each, and wound for



8 pole 3 H.P.

FIG. 9.

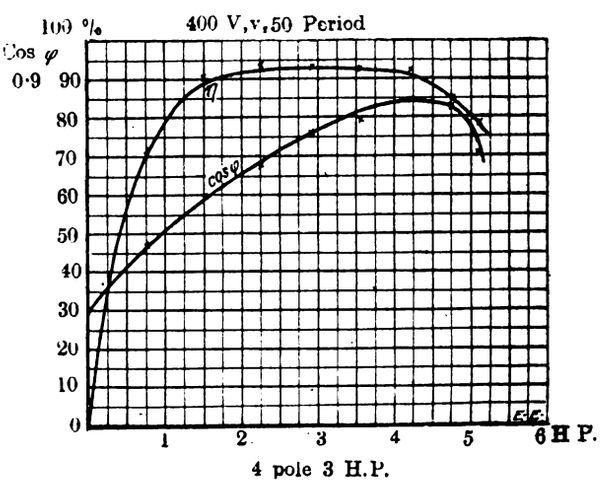
In order to avoid the excessive currents taken by motors with short-circuited rotors at starting, wound rotors with external resistances were introduced, and these permitted wide speed regulation, though at the same time the efficiency and output fell off at the lower speeds, whilst the power factor remained fairly constant. Figs. 3 and 4 show the connection between output, efficiency, and power



6 Pole 3 H.P

FIG. 8.

factor, and between speed and efficiency, for a 4-h.p. standard three-phase motor regulated in this way. As a further experiment the writer took readings of efficiency at various speeds, taking a constant power out of the machine, and obtained results similar to those shown in Fig. 4,



4 pole 3 H.P.

FIG. 10.

Digitized by Google

four, six, and eight poles respectively. Fig. 6 shows the standard four-pole stator winding, and Figs. 7, 8, and 9 show the efficiency and power factor for each element. The four-pole element has a starting torque corresponding to 2·9 h.p., the six-pole to 3 h.p., and the eight-pole to 2 8 h.p. at 400 volts and 50 ~. The winding of such a motor is simple, and at the same time there is always a reserve of power in hand in case of accident to any one element, as the latter can be repaired whilst the motor continues to work with the remaining elements.

ments in parallel. Figs. 13 and 14 give the winding and connections respectively for the above two-step motor. Since the changing over of a single element from one number of poles to another is open to the same objections as described at the beginning of this paper, a special switch, which also acts as the starting switch, is arranged to make each element at each speed start with its normal load, and the test results embodied in Figs. 9, 10, 11, and 12 were taken with this arrangement.

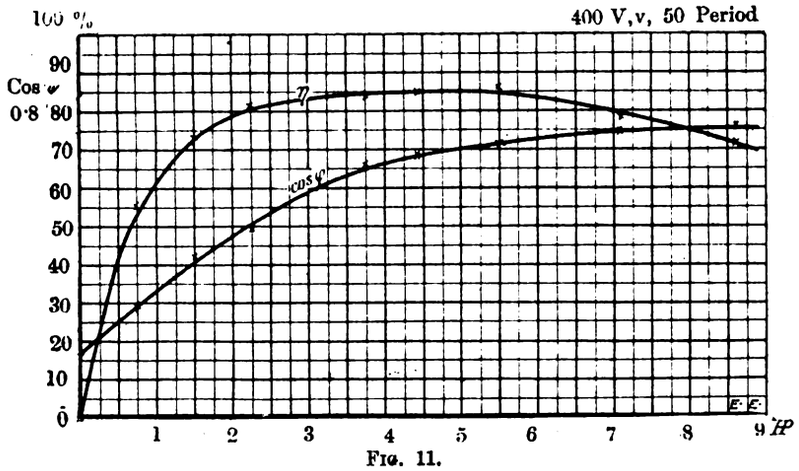


Fig. 11.

The above described motors have all been fitted with

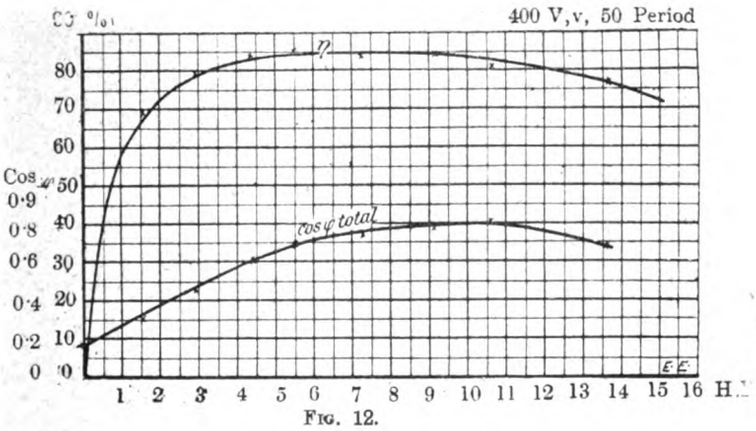

Fig. 12.

With a two-step motor three speeds and various powers can be obtained. A motor with, for instance, a four-pole element and an eight-pole one, each wound for 3 h.p., will run at 750 and 1,500 revolutions at 50 ~. By changing the eight-pole winding over into a four-pole one, 6 h.p. can be obtained at 1,500 revolutions, and by coupling this eight-pole winding changed over to four poles in parallel with the four-pole element, 9 h.p. can be obtained at 1,500 revolutions. By changing the four-pole winding into a two-pole one, 3,000 revolutions can be obtained. Fig. 10 shows the efficiency and power factor of the four-pole element of such a 3-h.p. motor. Fig. 11 shows the same for the eight-pole winding changed over into four poles, and Fig. 12 shows the combined effect of these two arrange-

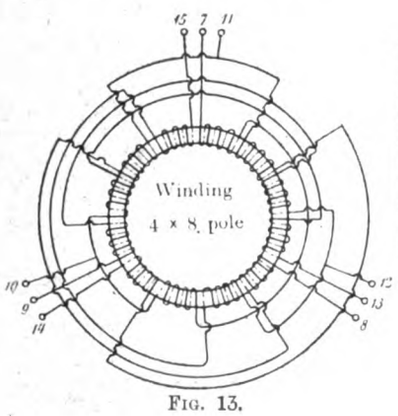

Fig. 13.

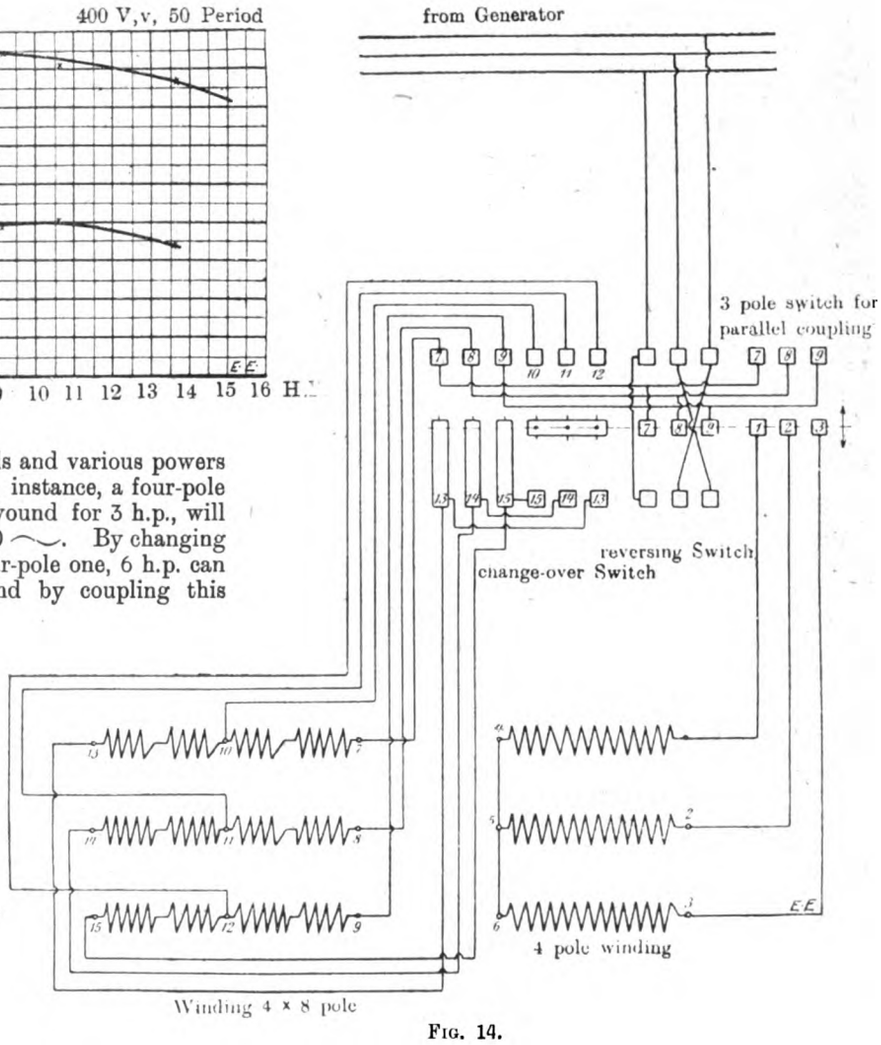

Fig. 14.

short-circuited rotors, but, of course, slip-ring rotors can also be employed. Fig. 15 shows a two-step 15-h.p. motor with four and eight pole elements, and Figs. 16 and 17 give its test results. Figs. 18 and 19 show a four-step motor intended for driving a large lathe for locomotive axles in which speed cones were to be avoided. The elements are wound with two, four, six, and ten poles at 500 volts 25 periods, and each element can develop 5 h p.

Digitized by Google

Such motors are, of course, more expensive and occupy more room than ordinary motors, but in certain applications both price and floor space are secondary considerations, as may be seen from the large number of installations already employing these motors. In order that the additional weight which the extra rotors put upon the bearings may not be harmful, the latter are made specially large.

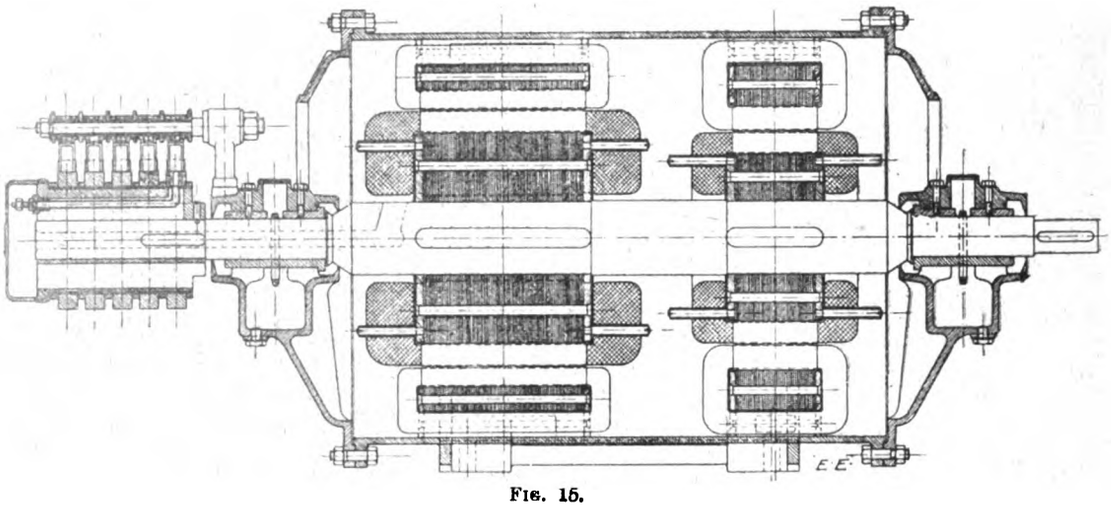

Fig. 15.

In conclusion, some experimental results obtained with a standard three-step 3-h.p. motor may be of interest. The elements were wound for four, six, and eight poles respectively at 410 volts 50 ⁓. The speeds obtained

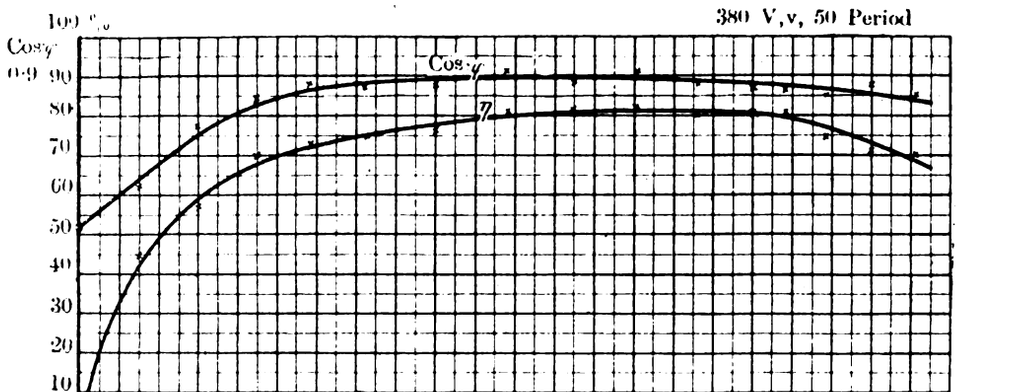

Fig. 16.

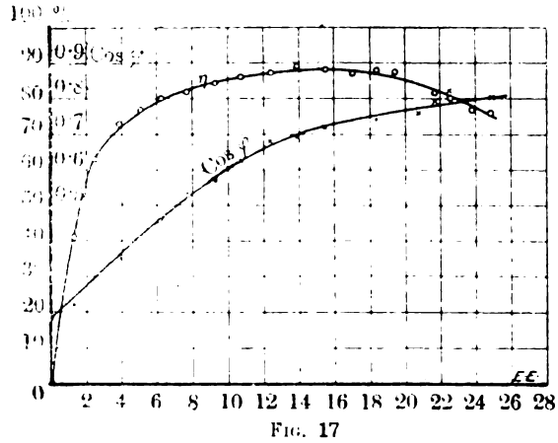

Fig. 17

with the three elements at light load were 1,500, 1,000, and 750.

With the 4 and 6 pole elements in parallel ...				1,060 revs.
„ „ 6 and 8 „	„	„	...	790 „
„ „ 4 and 8 „	„	„	...	770 „
„ „ 4, 6, and 8	„	„	...	820 „

When the six-pole element was opposed to the eight-pole one—*i.e.*, the coupling of one being arranged for one direction of rotation and that of the other for the opposite direction—the speed was 720 revolutions.

With the 4-pole against the 8-pole		730 revs.
„ „ „ „ „ 6-pole		950 „

With the 4 and 6 pole against the 8-pole the motor remained at rest.

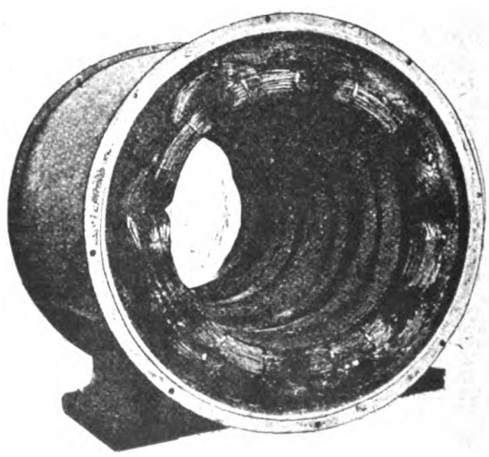

Fig. 18.

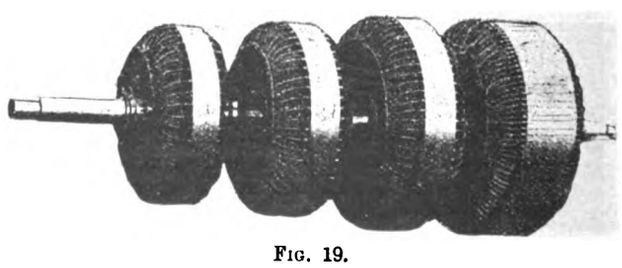

Fig. 19.

With the 6 and 8 pole against the 4-pole the speed was ..... 760 revs.

Digitized by Google

With the 4 and 8 pole against the 6-pole the speed was ..... 740 revs.

By connecting the four and six pole elements together a maximum load of 7 h.p. at 930 revolutions was obtained; the six and eight pole combination gave 8·7 h.p. at 690 revolutions; the four and eight pole, 6·7 h.p. at 670 revolutions; whilst all three elements together gave 10·6 h.p. at 690 revolutions.

TOTAL AND FREE ENERGY OF THE LEAD ACCUMULATOR.*

BY R. A. LEHFELDT, MEMBER.

In choosing a subject on which to address the opening meeting of the Faraday Society, it seemed to me I could not do better than deal with some points in the theory of the accumulator. It is a subject in which technical and scientific interests are thoroughly combined, and it is, perhaps, not very generally known how completely electro-chemical theory has been found to harmonise with the experience of technicians, how satisfactorily it brings together many experimental facts, and how suggestive it is. I have little to say to-night that is new. What I aim at is to bring into as clear a light as possible one salient aspect of physics as applied to the lead accumulator of the technical electrician. The chemical reaction of the accumulator I take to be

$$\tfrac{1}{2}Pb + \tfrac{1}{2}PbO_2 + H_2SO_4 \rightleftarrows PbSO_4 + H_2O.$$

(Read from left to right on discharge, from right to left on charge †)

That this, on the whole, accords with the facts there can be no doubt. The evidence in favour of it—chemical, electrical, and thermodynamic—is a more than sufficient proof. It is quite possible that certain minor points are not explainable without taking other actions into account. Elb's observations on plumbic sulphate, $Pb(SO_4)_2$, seem to show that that substance plays an important part, at least in the formation of spongy lead. But it will not be necessary for my present purpose to pay attention to such possibilities. Taking the above equation to be correct, I wish to point out how the general laws of energy allow one to draw conclusions with regard to the E.M.F. of the cell in which the reaction takes place.

For the purpose of analysing the transformations of energy involved, the reaction on discharge may be regarded as consisting of three parts: (*a*) from the electrolyte of the accumulator remove 1 mol. of sulphuric acid (H_2SO_4); (*b*) cause this to react with the dry solids, Pb_1 and PbO_2; (*c*) mix the mol. of water thus formed with the electrolyte. Action (*b*) is the same whatever the concentration of the electrolyte may be; actions (*a*) and (*c*), on the other hand, involve that concentration. Accordingly, we may separate the energy, and, therefore, the E.M.F. of the reaction, into a fixed part, depending on (*b*), and a part varying with concentration, depending on (*a*) and (*c*). We have then to determine the energy changes involved in these processes; the method is applicable to both the total and the free energy. It would be inappropriate to go at length into the distinction between these two quantities, yet I cannot help remarking that the distinction, which has occupied physicists for a quarter of a century, is not generally enough noted even now. And as the conception of free energy is the most important of all in physical chemistry, it can hardly be insisted on too much. It is, moreover, one of which it is very difficult to form any mechanical image. When a chemical system suffers a transformation, such as that involved in the action of the accumulator, it loses a certain amount (sometimes negative) of energy, and since all energy indiscriminately is capable of transformation into heat, it is only to perform the reaction in a calorimeter to find out how much. But all energy is not indiscriminately capable of doing work—despite its name—and with a chemical change a certain amount of ability to do work is associated, this amount being distinct from the change in total energy. Moreover, it is not mechanical work merely that is in this position; many kinds of energy, perhaps all except heat, are freely interchangeable amongst themselves, and yet not with heat. We have therefore to recognise two grades of availability in energy—not an indefinite gradation, which would perhaps be easier to understand, but two planes, so to say, a higher and a lower. With regard to the former, a chemical reaction has a certain energy value; with regard to the latter, another energy value which may be either greater or less than the first. The value on the higher plane—*i.e.*, of chemical, electrical, mechanical actions—is called the *free energy* of the reaction; that on the lower plane—of thermal actions—the *total energy*. And the total energy is "conserved" in any case; the free energy is conserved if the action remains within the limits appropriate to the higher plane.

(I.) *Total Energy.*—There are many ways of expressing the composition of a sulphuric acid solution. It will be most convenient to choose the molecular fraction in the present instance—*i.e.*, if z mols. of H_2SO_4 be mixed with $1-z$ mols. of H_2O, z is taken as the expression of the strength of the acid. As an instance of the meaning of this, I take an acid of ordinary strength, for which $z = 0{\cdot}05$. This may be stated in various forms as follows:

Molecular fraction	$z = 0{\cdot}05$
Composition	$H_2SO_4.19H_2O$
Percentage by weight	22 27 per cent. H_2SO_4
Grammes H_2SO_4 per litre.....	258
Normality	5·26 equivalent per litre
Density	1·161

Let χ be the heat of reaction of the pure materials (process (*b*) above) for the quantities shown in the chemical equation, and let Q be the heat of formation of the dilute acid used as electrolyte per mol.—*i.e.*, Q is the heat evolved by mixing z H_2SO_4 with $(1-z)$ H_2O. [In the example chosen, mixing 0·05 mol. or 4·9 grm. of strong sulpuric acid with 0 95 mol. or 17·1 grm. of water.] Q is found by experiment, and we have to express in terms of it the changes of total energy involved in (*a*) and (*c*). Suppose the reaction to proceed to an infinitesimal extent, so that dz mols. H_2SO_4 are used up, and dz mols. H_2O formed, for every mol. of electrolyte. Then the concentration which was formerly z has become $z - dz$. The heat evolved (negative in amount) in consequence of the removal of acid, and that (positive) due to addition of water to the electrolyte, are together expressed by $-\frac{dQ}{dz}dz$. Hence in processes (*a*) and (*c*) the heat is $-\left(\frac{dQ}{dz}\right)$, and the total heat of reaction of the accumulator is expressed by

$$\chi - \frac{dQ}{dz}.$$

This conclusion only in a less simple form, was, I think, first arrived at by Dolezalek, to whom the theory of the accumulator owes so much. Q has been determined by J. Thomsen, Pickering, and others. I have taken Pickering's numbers in the following calculations. When Q is plotted as a function of z the curve obtained is hardly regular enough to take differential coefficients off; I have therefore adopted the artifice of combining the graphical method with an empirical formula. Over the range required—*i.e.*, from $z = 0$ to $z = 0{\cdot}25$—the curve is roughly parabolic. I therefore choose a parabolic formula convenient for calculation—not necessarily the nearest to the truth that can be found—and draw a curve showing the differences between this and the experimental data.

Before giving the numbers it is necessary to remark on the unit used. Quantities of heat are properly expressed in joules—no electro-chemist, I hope, will use the unsystematic, inconstant, and unnecessary calorie. For electro-chemical purposes it is desirable to express all heats of reaction per equivalent, and not as in thermo-chemistry, for molecular quantities; but we may go a step further and divide the result by 96,600—the number of coulombs transported by an equivalent of matter.

* Paper read before the Faraday Society.

† I have written the above equation with the quantities required to convey our "faraday" of electricity (96,600 coulombs). This, I think, is a practice that electro-chemists might adopt generally with advantage.

Digitized by Google

The result will be a number of volts corresponding to the heat of reaction, and one may be permitted the slight inaccuracy of saying, for brevity, the "heat of reaction in volts." It must be remembered, of course, that the number of volts thus arrived at is not that actually given by the reaction, but that which would be given if all its energy were spent in producing current.

With this explanation, then, I may say that the heat of formation of sulphuric acid solutions is roughly

$$Q = 0{\cdot}8\ z - 1{\cdot}2\ z^2 \text{ volts.}$$

The deviations from this formula are too large to ascribe to errors of experiment; I have therefore plotted them on a large scale diagram. To determine $\frac{dQ}{dz}$ I calculate from the above formula $0{\cdot}8 - 2{\cdot}4\ z$, which forms the greater part, and get the small correction by tangents to the curve. The results are given in the following table:

z	$\frac{dQ}{dz}$ (volts)	
0	0·787	From Pickering's measurements. Temperature, 18deg.
0·0025	0·781	
0·01	0·765	
¼	0·680	
0·05	0·674	
⅛	0·579	
0·10	0·557	
0·15	0·440	
¼	0·407	
0·20	0·340	
0·25	0·253	

appears that this has been over-estimated: the true heat of reaction is probably less than even Streinitz's value. Taking the mean value of χ and combining it with the tabulated values of $\frac{dQ}{dz}$ as the most trustworthy final results, we get what is shown in Fig. 1, Curve A. This is the *total energy* of the reaction:

$$\tfrac{1}{2}Pb + \tfrac{1}{2}PbO_2 + H_2SO_4 \rightleftarrows PbSO_4 + H_2O$$

expressed by its equivalent in volts for various strengths of acid.

TEMP. 15°.

					Mean	2·625

(II.) *Free Energy.*—The free energy of a reaction may be estimated in various ways, and two of them have actually been worked out for the accumulator. (i.) The first is to

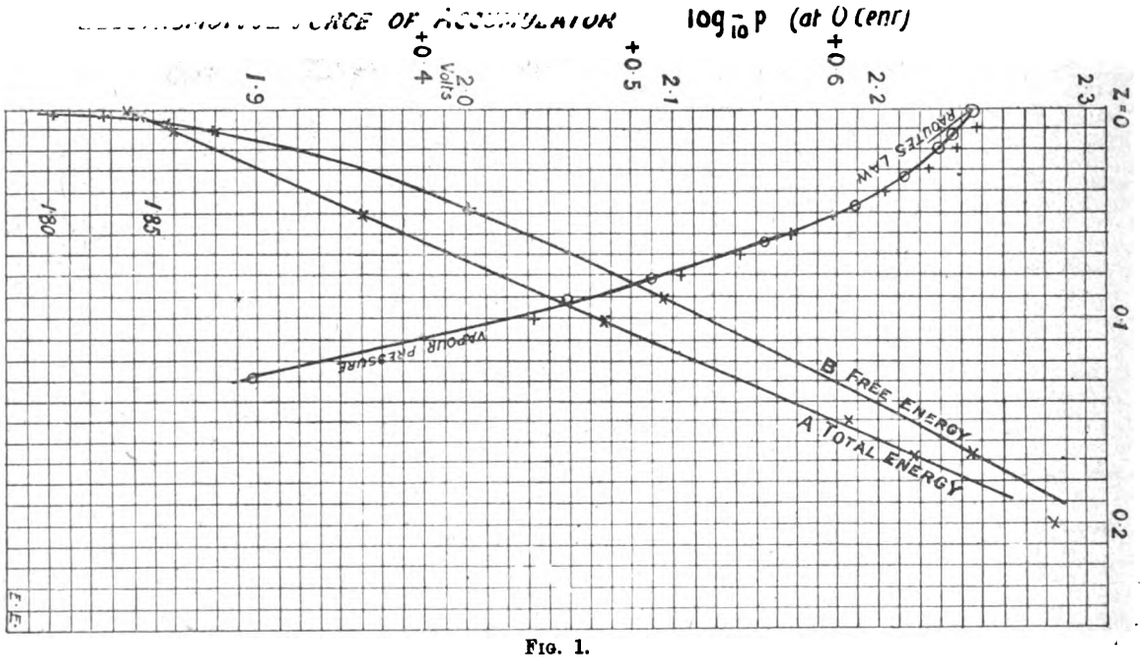

FIG. 1.

These numbers give the variation of the total energy of reaction; but we have also to find χ in order to know the total energy itself. Two methods are available. The heat of reaction has been found calorimetrically in the case of acid of strength $z = 0{\cdot}0025$. Tscheltzow gives for the molecular quantities, 88,800 calories = 186,580 joules per equivalent, or 1·931 volts; Streinitz, from a different series of reactions, 86,800 calories = 182,280 joules = 1 887 volts. Secondly, we may adopt the thermodynamic formula $\left(E - T\frac{dE}{dT}\right)H$ for the heat of reaction, where E = E.M.F., T = absolute temperature, H = quantity of electricity. If we adopt the same mode of expression for the quantities of energy as before, H = 1, and the "heat of reaction in volts" is given by $E - T\frac{dE}{dT}$ merely. The degree of consistency between the data may be judged by the following table, in which χ is calculated by both methods.

The numbers in the last column should, of course, be constant; they actually vary by 1 to 2 per cent. from the mean, which, considering the numbers and difficulty of measurements involved, is fairly satisfactory. χ, as calculated from the heat of reaction, is certainly too high, so it measure the E.M.F., E. For this multiplied by the quantity of electricity, F, flowing gives the electrical work done, E F; or, abbreviating as before, we may express the equivalent of the free energy by the voltage, E, merely. Herein lies the extreme importance of E.M.F. measurements in physical chemistry. (ii.) We may compare the free energy values in two solutions of different strength by studying a process of distillation. If two accumulators with electrolytes of different densities be put in opposition, the stronger will charge the weaker; the total amount of Pb, of PbO_2, and of $PbSO_4$ will be unchanged; but there will be less strong acid and more weak after the action is over. Now, just the same thing could be accomplished by distilling some water from the weak accumulator into the strong one, and some H_2SO_4 from the strong into the weak. I need not go into details of the process, as these have been worked out by other writers; but it is clear that if we take E as the measure of the free energy of the accumulator reaction with acid of a certain standard density, we can find what it is for any other strength of acid in terms of vapour pressures.

I have collected and recalulated the best data I can find as to these two methods, and the results are shown in the figure. Curve B gives direct measurements of E.M.F. The

Digitized by Google

other curve shows Dieterici's measurements of vapour pressure at 0deg. But as the process of calculating electromotive power from this is not a satisfactory one I have reversed it, and calculated the vapour pressure from the E.M.F.; the results are shown by small crosses near the vapour-pressure curve. The vapour pressure for $z = 0.05$ is assumed. It will be seen that the other points lie near the curve of observation, but the agreement leaves something to be desired. The curve of free energy follows that of total energy in its general course. The difference between the two represents, as is well known, the "latent heat" of the cell; or, otherwise stated, the term $T\frac{dE}{dT}$; it is consequently a measure of the temperature coefficient of the cell. This is positive over most of the range, but negative for very dilute acid, and zero for $z = 0.006$. For that concentration alone the free energy is equal to the total energy. This point was determined by Dolezalek by direct experiment, as $z = 0.012$. Here, again, though the experiments support the theory in a general way, the agreement is not quite what might be hoped for if the constants of sulphuric acid solutions were systematically redetermined.

APPENDIX.

If Ω is the change of free energy corresponding to the reaction (in equivalents)—

$$\tfrac{1}{2}Pb + \tfrac{1}{2}PbO_2 + H_2SO_4 = PbSO_4 + H_2O,$$

when undiluted H_2SO_4 is used, and if w is the free energy of formation of the mixtures $z\ H_2SO_4 . (1-z)\ H_2O$, then the change of free energy due to the above reaction when taking place in a solution of strength z is

$$\Omega - \frac{dw}{dz}.$$

The E.M.F., E, of an accumulator is, therefore, found by dividing this quantity by the "faraday" F (= 96,600 coulombs)—or,

$$E = \frac{1}{F}\left\{\Omega - \frac{dw}{dz}\right\} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Now, $\frac{dw}{dx}$ may be found in terms of vapour pressures as follows: Give 1 mol. of mixture of strength z, and a small quantity dz mol. of H_2SO_4, mix these, and remove from the mixture dz mol. of H_2O. We have then obtained 1 mol. of mixture of strength $x + dz$, or in chemical symbols—

$$z\ H_2SO_4 . (1-z)\ H_2O + dz\ H_2SO_4 = (z+dz)\ H_2SO_4 . (1-z-dz)\ H_2O + dz\ H_2O.$$

The change of free energy in this reaction is, therefore, $\frac{dw}{dz}$. To evaluate it, suppose the acid added and water removed reversibly by isothermal distillation. Let $p_0\ p$ be the vapour pressures of pure water and of water in the given mixtures respectively; $p'_0\ p'$, the vapour pressures of pure sulphuric acid and of sulphuric acid in the given mixture respectively; R, the gas constant; T, absolute temperature. Then it is well known that

$$\frac{dw}{dx} = RT\left\{\log_e \frac{p'_0}{p'} - \log_e \frac{p_0}{p}\right\} \quad . \quad . \quad . \quad (2)$$

Hence

$$\frac{d^2w}{dz^2} = RT\left\{\frac{d\log_e p}{dz} - \frac{d\log_e p'}{dz}\right\} \quad . \quad . \quad (3)$$

But in virtue of the thermodynamical relation

$$z\frac{d\log_e p'}{dz} + (1-z)\frac{d\log_e p}{dz} = 0 \quad . \quad . \quad (4)$$

We may eliminate from (3) the vapour pressures of sulphuric acid, which are too small to measure, and obtain

$$\frac{d^2w}{dz^2} = \frac{RT}{z}\frac{d\log_e p}{dz},$$

or, from (1)

$$\frac{dE}{dz} = -\frac{RT}{zF}\frac{d\log_e p}{dz} \quad . \quad . \quad . \quad . \quad (5)$$

This equation may be made use of either to determine E from p, or p from E; but in practice, allowing for the difficulty of obtaining trustworthy empirical formulæ, it is the latter that is more satisfactory. For this purpose we may write

$$\log_e p = -\frac{F}{RT}\int z\frac{dE}{dz}\,dz.$$

Direct evaluation of this integral involves the impracticable process of obtaining differential coefficients of the observed E.M.F.'s. It is therefore necessary to integrate by parts

$$\log_e p = \frac{F}{RT}\left\{\int E\,dz - Ez.\right\}.$$

The results given in the text and accompanying plates have been obtained graphically from data given by Dolezalek. They are given in terms of the cadmium cell as 1·0220 volt. I have therefore reduced them in accordance with more recent determinations of the standard cell as being 1·0187 volt. Thus reduced they are

z	E	z	E
$\frac{1}{101}$	1·881	$\frac{1}{11}$	2·096
$\frac{1}{21}$	2·001	$\frac{1}{6}$	2·245

COST OF ELECTRIC LIGHT IN SMALL HOUSES.

BY R. S.

In many towns where an electric supply is available numbers of small houses are now being built which are wired for electric light instead of having gas-piping put in, and it may be of use to intending occupiers of such houses to know the actual yearly cost of electric lighting from the experience of one who has tried it.

A year or two ago the writer took an eight-roomed house in one of our Midland towns at a rent of £30. The house, which was a new one, was wired for electric light, and had no gas-piping laid on, so that the choice of illumination lay between electricity and oil. The following table gives the sizes of the rooms, number of lamps installed, and number actually used, and it will be seen that the total candle-power installed is 152; but the maximum candle-power of lamps alight at any one time would probably not exceed 100. The lamp in the scullery was found to be unnecessary, and was taken off, as the scullery was sufficiently illuminated by the kitchen lamp.

Room.	Size, feet.	Number and candle-power of lamps installed.	Number of lamps actually used.
Dining	13 × 13	three 16-c.p. lamps	one, all evening
Drawing	14 × 12	ditto	one, occasionally
Hall	—	one 8-c.p. lamp	all evening
Kitchen	13 × 12	ditto	ditto
Scullery	9 × 8	ditto	removed
1st bedroom	18 × 13	one 8 c.p. lamp	every night
2nd ditto	14 × 12	ditto	ditto
3rd ditto	12 × 10	ditto	occasionally
Landing	—	ditto	ditto
Bathroom	9 × 6	ditto	ditto
Attic	—	none	—

The current is supplied at a voltage of 200, and was charged for the first six months of the year under discussion on a maximum demand system commencing at 6d. per Board of Trade unit, and for the remaining six months at a flat rate of 5½d. per Board of Trade unit. The average price for the year worked out to 5·34d. per Board of Trade unit, and the number of units registered by the meter during the 12 months ending June 30, 1903, was 193, the electric light bill for the same period being £4. 6s. The current is supplied by the Corporation, and no meter rent is charged.

As the writer's family retire to rest early, and are careful to switch off all lights when not required, the above number of units may be taken as the minimum required for the yearly lighting of a small villa such as the one described above. The author estimates the cost of electric lighting in his case at about 33 per cent. more than gas lighting, but in many towns the cost of current is less than in the case above. Of course, the cost of new lamps must be added to the electric light account, but this is not a large item. With lamps costing 9d. each, the author finds that those downstairs last nearly a year, and the bedroom lamps 18 months or more, before they become too dim for use. He is now experimenting with 5-c.p. lamps in the hall and bedrooms, and finds that these give quite sufficient light in places where it is not required to write.

ELECTRIC AUTOMOBILE ACCUMULATOR CELLS FOR QUICK CHARGE RATES.

BY E. KILBURN SCOTT, M.I.E.E., A.M.I.C.E

Much interest is being manifested at the present time in the question of accumulator cells for automobile work. The tyre difficulty, which previously gave so much trouble, has apparently been overcome, and in the matter of motors and controllers the new electrical vehicles are practically perfect. It only requires a thoroughly satisfactory cell to place the electric automobile in front of every other for general convenience, ease of and quietness of running, and possibly also durability and cost of upkeep. The great desideratum of an automobile cell is a *high charge rate*, so that when making long journeys the car can run to any electrical station and have the battery completely charged in, say, three-quarters of an hour. The ideal thing would be to drop half-a-crown in a slot and get juice forced into the cells whilst the driver is having a drink, but possibly this is asking too much at present; it will no doubt come to something like that in time.

Practically all cells at present on the market have the objection that the plates buckle under a quick charge or discharge. Let us consider for a moment what are the mechanical reasons for a plate buckling. All plates so far have consisted of a rectangular lead grid or plate, or else a rectangular frame, as in the D.P. cell, with strips of sheet lead laid across. Now during charging, expansion of the active material takes place, and if the charge is too rapid such expansion is proportionately great. As the actual lead plate or frame does not expand so quickly as the active material, there is nothing for the latter to do but to bend outwards, or, in other words, buckle. By a proper recognition of the simplest laws of mechanics it should be possible to design a plate in which the active material may expand and contract quite freely. Yet for some reason or other this has not been done. The situation, in fact, reminds the writer of the time when the diamond-frame safety bicycle was introduced, and those associated with its manufacture had not the engineering gumption to employ a cross-bar, and so change a redundant frame into two *rigid* triangles. A few minutes' study of a five-barred gate would have shown the reason why. Accumulator manufacture appears to have been through much the same stage, for the designers have been so busy with chemical equations and methods of making lead porous, etc., that they omitted to look at the plate itself simply as a problem in mechanical design. The men in accumulator work, as in so many other branches of electrical activity, have, in fact, been too much the electrician and too little the engineer.

The writer has had an opportunity recently of investigating two forms of cell which are about to be put on the market in which this buckling trouble is done away with. The first is the Elieson plate cell, and the second a solidly-built cell designed by Mr. Niblett. The Elieson plate is on the lines of the D.P., but the strips of lead are alternately straight and crimped. They are united together by a central core of lead, from each side of which the strips extend like the hairs from a feather. At the top and bottom cross pieces of wood give support to the ribs or vanes. As the strips are only held at one end, the oxidised material is absolutely free to *expand and contract*, and consequently buckling is obviated. An Elieson cell containing three negatives and two positives, measuring 8in. by 5½in. by ⅜in., and weighing 22½lb. complete with acid, is rated at 115 hours' capacity on a five hours' discharge rate. Such a cell was tested at the Reading electricity works, with the following results: The cell being nearly fully charged, was discharged at a rate of 20 amperes down to a voltage (on load) of 1·50 volts. It was then completely charged in 75 minutes, commencing at a rate of about 120 amperes and finishing at a rate of 45 amperes, the total charge being 110·69 ampere-hours. It was again discharged at the 20-ampere rate, and continued until the voltage dropped to 1·5, the total discharge capacity being in this case 101·66 ampere-hours, thus showing an ampere-hour efficiency of approximately 92 per cent., which, considering the high rate of charge, is remarkably good. The discharge was then continued at the 20-ampere rate until only 0·50 volt was registered, and the cell was then short-circuited and left for 48 hours. A charge of 128 ampere-hours was again made in one hour, the rate for about 20 minutes being nearly 150 amperes. An extra 40 ampere-hour charge was then made in one hour, and the cell left for four days. At the end of this time a discharge made at the high rate of 50 amperes for 1½ hours, and for a further 45 minutes at lower rates, showed a capacity of 106 ampere-hours, clearly demonstrating that no loss of capacity had been caused by the severe ill usage to which it had been subjected, the overcharge having been sufficient to reduce all the sulphating caused by the over-discharge, and to restore the cell to its normal condition. Sir W. H. Preece tested a similar five-plate cell, and found that it could easily absorb its charge in three-quarters of an hour, and this high rate of charge had no apparent deleterious effect on the cell, for the whole current consumption of the charge is so absorbed that there is, even after 250 amperes going in, no gas given off.

The new Niblett cell is being made at Horton Kirby, Kent. It mainly consists of a lead-lined box, the lining forming one pole, a porous pot containing and being surrounded by active material, and a central solid rod of lead for the other pole. The distance between the rod and inside of the porous pot is about 1in., whilst the space outside the porous pot to the lead lining varies from 1in. at the shortest point to 2in. at the corners, due to the pot being round and the containing box square. The active material consists of alternate layers, each about 1in. thick, consisting of pieces of lead rendered flaky by being melted and dropped into water, and of pellets of litharge about $\frac{3}{16}$in. diameter. These are pressed down fairly tight, first a layer of lead and then one of litharge, until the whole space, both inside and outside the porous pot, is quite full. The acid finds its way into the small spaces left between the pieces of lead and of the litharge, and expansion is taken care of by these spaces. There is, of course, no question of any buckling in such a cell, but unfortunately weight is against it, whilst the porous pot increases the internal resistance, and is, of course, liable to get cracked. At the same time this seems to be the only feasible way of making a pasted cell without having the buckling trouble. The Crowdus plate is a pasted one, and has given some good results, yet the writer considers that paste is not really feasible for automobile work unless the material is packed in solid as in the Niblett cell. If a plate is employed at all, it seems to the writer that it *must* be of the Planté type, and, judging by the results obtained by Mr. Elieson, a Planté cell can be made to compete with the lightest form of pasted plate cell in the direction of capacity in watt-hours per pound of weight.

TURBINE-GENERATORS.

The expiration of the original patents of the Hon. C. A. Parsons for steam-turbines is opening the market to a large number of firms who are taking up new types of turbines. This in the long run must result in a largely extended use of these prime movers. Amongst the firms to embark on this kind of work are Messrs. Willans and Robinson, of Rugby. We understand that they are building for Messrs. R. and W. Watson, of Linwood, N.B., a steam-turbine which is to be capable of giving 1,000 kw. from a continuous-current generator on the shaft. The generator is to be built by the British Schuckert Electric Company, and will give 4,000 amperes at 250 volts. Instead of being one machine, it will consist really of two 500-kw. dynamos placed in tandem on the turbine shaft. In this connection it will be borne in mind that the design of turbine-driven alternators is a comparatively simple matter, but that the question of commutation renders the construction of large output, high-speed, direct-current dynamos by no means easy. After giving careful consideration to this point, the British Schuckert Company have guaranteed that these machines shall run sparklessly with fixed brushes at all loads. Details of the machine we hope to give at a later date. Another firm which has taken up the same class of work has found it necessary to add subsidiary poles over the armature wound with a few turns of wire carrying the main current, in order to get sparkless commutation under the above conditions. We believe, however, that the combination above referred to will be the largest direct-current turbine plant in the United Kingdom.

NOTES.

Felling Trees by Electricity.—Our Continental exchanges state that successful experiments have been made in various forests in France in the felling of trees by electricity. A platinum wire is heated to a white heat by an electric current and used as a saw. In this manner the tree is cut through much easier and quicker than in the old way, no sawdust is produced, and the slight carbonisation which results acts as a preservative of the wood. The new method is said to require only one-eighth of the time consumed by the old sawing process.

A New Telegram Code.—Messrs. W. Clowes and Sons announce the production of a new telegram code for use in cipher telegraphy. The work, of which Messrs. C. A. Moreing and Fredk. G. McCutcheon are the joint authors, is in three volumes. The aim has been to prepare a practically universal combination cipher code which shall facilitate and economise cable correspondence. It is claimed for the new system that its use will effect an average saving of something like 65 per cent. over ordinary methods. The price of the complete work is £21.

The Metric System.—Since this question was discussed before the Institution of Electrical Engineers last session, it has been debated with more or less vigour in many another assembly in different parts of the country. We understand that a conference will be held in London at the end of the present month of representatives of local authorities who have come to a decision by resolution on the subject. The conference will be invited to appoint a representative deputation to meet the Board of Trade to discuss the question of the compulsory use of metric weights and measures in this country.

Vesuvian Electric Railway.—An electric railway has been built up Mount Vesuvius to act as a feeder to the existing cable railway. The line is nearly five miles in length, and is divided into three sections. The first and third sections are ordinary lines, on which self-propelled electric cars are run. The middle section differs from the other two in that it is a rack railway, on which the cars are pushed up by an electric locomotive. The cars accommodate 24 passengers sitting. The journey up the mountain side is an exhilarating and enjoyable one, providing magnificent views of the surrounding country.

Brighton Municipal Telephones.—The extension of the Brighton Corporation telephone system to Burgess Hill was successfully inaugurated on Saturday afternoon. Congratulatory messages were exchanged between the Burgess Hill Urban Council offices and the Theatre Royal, Brighton, and also with London. The Corporation telephone exchange has now over 1,300 subscriptions, and new connections are being asked for at the rate of over 50 a fortnight. The ultimate success of the undertaking is looked upon locally as already assured. The Brighton system was recently described in this journal.

Electric Lighting in Rome.—Many ancient and historic buildings are now losing some of their antiquity by the introduction of the electric light, whose subtle encroachments apparently no hand can stay. Among the latest to succumb to the anachronistic illumination of electricity is no less a venerable pile than St. Peter's in Rome. The installation has recently been completed. Current is supplied at 2,000 volts alternating, and is reduced to a lower voltage by transformers situated in a chamber on the level of the main cornice round the dome. The interior lighting consists of 628 incandescent lamps of 25 c.p., and a large number of others of 10 c.p. The total illumination at present is 14,000 c.p. The installation, however, is capable of being increased to a maximum of 80,000 c.p. An interesting feature of the work is that the high-frequency mains are two miles in length, while the copper wire used in the building itself extends to a total length of 15 miles.

Institution Provisional Arrangements.—A provisional programme of papers proposed to be read before the Institution of Electrical Engineers in London up to the end of the current year, was announced at the opening meeting yesterday week. It is as follows: Nov. 26—"The Testing of Electric Generators by Air Calorimetry," by Mr. R. Threlfall, F.R.S., member; "The Edison Accumulators for Automobiles," by Mr. W. Hibbert, associate member. Dec. 10—"The Ondograph," by Mr. E. Hospitalier, foreign member; "On the Magnetic Dispersion in Induction Motors, and its Influence on the Design of these Machines," by Dr. Hans Behn-Eschenburg. Dec. 17—"The City and South London Railway: Working Results of the Three-Wire System applied to Traction, etc.," by Mr. P. V. McMahon, member. This programme is necessarily subject to alteration, but in its present form it will serve to indicate the nature of the subjects which are to be brought before the Institution for discussion up to Christmas.

Selective Wireless Telegraphy.—We understand that some important experiments are being carried out in the States with a system of wireless telegraphy devised by Mr. John Stone. The feature of the Stone system is that it is an attempt to secure selective signalling by the use of simple harmonic electrical oscillations. The practical application of the method was not easy, but the initial work of Mr. Stone has resulted in the construction of apparatus by which he is able to signal selectively across a difficult piece of country between Cambridge and Lynn, in Massachusetts, without being interfered with at all by other electrical disturbances. It is stated that the selectivity of the system can at present be controlled within 10 per cent., but this will, no doubt, be improved by further work. It is thought that once a selective system has been brought to a commercial point, it will not be difficult to secure secrecy also. The Stone system of wireless telegraphy is fully illustrated and described in the issue of the New York *Electrical World* for Oct. 24. We have yet to learn that tuning gives secrecy.

International Wireless Telegraphy.—An official note has been issued of the proceedings of the Berlin Conference on Wireless Telegraphy containing the text of the final protocol. As everyone knows, the conclusion arrived at by all the countries represented, with the exception of England and Italy, was that an international convention should be drawn up binding all coast stations to receive and transmit messages from and to ships without distinction of the systems employed by the vessels, and fixing the basis on which the rates should be charged. It now transpires that the objection of the British delegates to any such agreement was based on the ground of the uncertain position of wireless telegraphy in Great Britain at the present time. On the other hand, Italy would not sign the protocol because of the clause binding the contracting States to make public all technical information of a kind to facilitate communication with ships. The Italian Government, it will be recalled, in its agreements with Signor Marconi has agreed to keep secret all details of installations. We understand that it is proposed to hold another international conference on the subject next year.

Electricity in Australasia.—Electrical developments in our most southern colonies is not so rapid as we should like to see it. Recently published statistics show that the

Digitized by Google

total number of electric supply stations in Australasia has increased in the past 12 months by only two. The new stations are the municipal plant which has been laid down by Dunedin Corporation, New Zealand, and another at Devonport, in Tasmania. The total plant capacity has increased in the same period from 14,303 kw. (19,000 h.p.) to 16,877 kw. (22,500 h.p.). This does not include the extensive electric tramway power-houses of Sydney, Brisbane, Perth, Kalgoorlie, Auckland, and Hobart. Of the 36 stations, 23 are privately owned and 13 are municipally owned. Rapid progress is being made in the modernisation of the systems in operation. Sydney is introducing a new three-phase, four-wire, low-tension distribution, and Launceston is changing over from a single-phase, 2,000-volt, 100-cycle, to a three-phase, 5,000-volt, 50-cycle system, with a four-wire, low-tension network. There are three three-phase systems, four combined alternating and direct current systems, 12 single-phase systems, and 17 direct-current systems. A large proportion of the low-tension networks are now operating on the three-wire system. Every effort is being made to standardise the low-pressure voltage to 110 or 220.

Tunbridge Wells Telephones.—"The work of transferring the wires from the late Corporation system to that of the company has now been completed, and it is hoped that the subscribers are in consequence getting a more rapid service." Thus the National Telephone Company in their latest circular to the inhabitants of Tunbridge Wells concerning the telephone system. The hope expressed therein, however, appears to be ill founded, for at the present time we hear of complaints which are being made by the subscribers against the inefficiency and slow working of the company's undertaking in the town. An attempt is being made to throw the blame for this on the old municipal system, for, in the words of the circular, "during the recent continued wet weather, owing to the faulty construction of the late Corporation lines, their insulation has proved to be so defective that when connected to the company's more sensitive system they have developed faults which have seriously interfered not only with their own working, but with that of the whole system." This, of course, may be the *ex parte* statement of the company in want of an excuse. In any case this would not prevent the subscribers getting replies to their calls if there were proper attention at the exchange. It is useless at this time to throw discredit on the late municipal lines—which, by the way, the company were anxious enough to buy—and the subscribers at Tunbridge Wells are acting quite within their rights in insisting in their demands for a more efficient and expeditious service.

Slaby-Arco Wireless Experiments.—In connection with the recent international conference on wireless telegraphy at Berlin, a preliminary report of Prof. Slaby's experiments has been presented to the council of the Jubilee Fund of German Industry, which granted that experimenter a subvention of £1,000 for continuing his researches. These experiments first dealt with the question as to the part played by the earth in connection with space telegraphy. By means of extensive zinc plates on the ground of his laboratory the author was able to construct a sort of artificial earth and to study the propagation of electric waves along the ground. He announced the presence of stationary waves, giving evidence of the important rôle played by the conductive surface of earth. The theory of closed sending apparatus was not so far able to account for the distance effects of such sender types. Prof. Slaby now succeeds in reducing these effects to the action of the upper harmonics, and in establishing a novel theory, the results of which are in a most satisfactory accord with experiments. The author further dealt with the design of instruments, enabling even unskilled persons to measure the wave-length of a transmitting apparatus. About a dozen different types have been experimentally studied and shown to be fully suitable. The author, we learn, is at the present engaged in studying new sender types, it being anticipated that a better method of tuning different stations will be derived from these experiments, which are shortly to be recorded in an extensive treatise.

Speed of Electric Tramcars.—Mr. R. Moffat Ford, who has at length succeeded in obtaining convictions against four drivers of electric tramcars in West London for exceeding their legal speed limit of 10 miles an hour, writes us an explanatory letter of his action in the matter. He repudiates the suggestion of vindictiveness which has been thrown out against him, and declares his motive to have been to show in some practical fashion the absurdity of putting it in the hands of local authorities to enforce a speed limit of 10 miles an hour in the case of motorcars under the new Act. He wanted to show the public what a speed of 10 miles an hour really is, and in pursuit of his object he selected the popular electric tramcar for the "demonstration." We do not know whether he succeeded in showing that a speed of 10 miles an hour is altogether too slow in these days of rapid transit, but in any event the question remains whether the end justified the means. But although Mr. Ford expressly repudiates any such motive as vindictiveness on his part, his letter leaves no doubt that he is incensed, to say the least, at the campaign of "motor-catching" which, he says, has been indulged in for the past seven years by the police all over the country, although all element of danger has repeatedly been admitted to be absent. If the charge of vindictiveness may not be lightly laid against Mr. Ford, we should be inclined to conclude from this that he is at least a disciple of the retaliatory doctrine which His Majesty's Government is so anxious that the country should adopt in its future fiscal policy.

New Books.—"Cylinder Oil and Cylinder Lubrication," by Messrs. Henry M. Wells and Wm. Scott Taggart, M.I.Mech.E. Part I. (the Henry Wells Oil Company, Manchester. 3s. 6d.).—To all engineers who desire to gain a further knowledge of the complex subject, cylinder lubrication, we commend this book. Mr. Henry M. Wells, joint author with Mr. Wm. Scott Taggart, is a well-known cylinder oil specialist, and the value of the work is enhanced by an interesting introduction written by Prof. Hele-Shaw, F.R.S. In this Prof. Hele-Shaw testifies to the great importance and, at the same time, the difficulty and complexity of the subject, and refers to some tests which the Henry Wells Oil Company have carried out, and from the results of which presumably the present issue has been compiled. These experiments are still proceeding, and from time to time the results will be published. The book treats of cylinder oil, its origin and production, and the processes through which the crude oil passes from the well to the finished product. A valuable feature is an analysis of numerous cylinder oils giving results hitherto unobtainable, and most of which were previously non-existent. Deductions from these analyses and a section dealing with some practical aspects of cylinder lubrication will be found to be among not the least interesting pages of the work. The book is illustrated by drawings of the chief types of British, Continental, and American steam-engines, and shows also some examples of the most important types of cylinder lubricators. That the present methods of judging a lubricating oil by analysis and physical tests are very fallacious, if not foolish, is only one of the many useful

Digitized by Google

morals to be drawn from this interesting work.—The author of "Tube, Train, Tram, and Car" (Geo. Routledge and Sons. 6s.) is Mr. Arthur H. Beavan, not Beaven, as previously stated.

Photometric Tests of Nernst Lamps.—The fourth report of the N.E.L.A. Committee of America for investigating the photometry of arc lamps, etc., has recently been issued, and some valuable tests of Nernst lamps are recorded. The work has been carried out by Prof. C. D. Mathews at the Purdue University. The Nernst lamps experimented with were of the one, three, and six-glower types, equipped with shades and accessories as put upon the market by the manufacturers. The report calls attention to the need for constancy of voltage when operating Nernst lamps. Thus, a special test revealed the fact that near the working voltage 1 per cent. variation made a change of 14 per cent. in candle-power. With the lamps experimented with a constant current of 0·4 ampere per glower gave a most satisfactory result from a photometric standpoint. The report deals most fully with the distribution of light from the three types of lamps, and finally with the mean hemispherical and spherical candle-power. With clear globes the average watts per mean hemispherical candle-powers for the three types of lamps were as follows: with one glower, 2·31; with three glowers, 2·33; and with six glowers, 1·88. The mean spherical candle-power is, of course, less, and the watts expressed as per mean spherical candle-power with a clear globe of six glowers were 3·30. These figures clearly show that the six-glower lamp is considerably more efficient than either the one or three glower. The reason for this would appear to be that with a number of glowers in close proximity mutual radiation allows them to operate at a higher temperature than would an isolated glower, with the same expenditure of energy. The result is an increase of light output, in spite of screening effects between different glowers. In a curve given in the report the Nernst lamp is compared with both alternating and direct current arcs. The difference in the polar diagram of candle-power is very considerable, and the result does not give much hope that the Nernst lamp will be able to replace the arc lamp of equal candle-power.

Obituary.—It is with great regret we have to record the death of Mr. James Hookey, late engineer-in-chief at the General Post Office, which took place at his London residence on Saturday. Our readers will remember that Mr. Hookey retired from the responsible duties which attach to the office of head of the engineering department at St. Martin's-le-Grand only last year, when he was succeeded by Mr. John Gavey. His numerous friends in the profession we are sure will join with us in extending our deep sympathy with Mr. Hookey's family in their bereavement. Born at Bristol on Dec. 30, 1839, he was thus in his sixty-fourth year. At the age of 15, after being educated at Bath, Mr. Hookey commenced his professional career with the old Electric Telegraph Company, in six years attaining to the position of engineering inspector and assistant superintendent of the company's West Midland section. A year later, in 1862, he was transferred to the London headquarters, serving as chief officer under the late Cromwell F. Varley and his successor, Mr. Richard S. Culley. Thus, at the early age of 22, he was called upon to fill one of the highest positions it was possible to reach in his profession in those days. When the telegraphs were taken over by the State, Mr. Hookey went to the Post Office, notwithstanding a tempting offer he received from one of the great railway companies as superintendent of its telegraph system. From 1870 until 1882 he retained his position as chief officer, first under Mr. Culley, who also went to the Post Office, and afterwards under Mr. Graves, who succeeded Mr. Culley. In the latter year he was appointed principal technical officer under Mr. Graves and Mr. (now Sir) William Preece, these two gentlemen being respectively chief engineer and electrician. Ten years later he became assistant engineer-in-chief on the death of Mr. Graves, when the two offices were combined in Mr. Preece. On the retirement of Sir William Preece in 1899, Mr. Hookey was appointed engineer-in-chief, in which position he was succeeded by Mr. Gavey, as already stated, in 1902.

Electrical Power in West Africa.—The use of electrical power in gold mining is a comparatively new application, and up to the present but few such installations have been put into operation. The one notable instance of employing electricity for this purpose is, of course, at the Kolar goldfields, in the Mysore State of India, where the electric power is transmitted over a distance of 92 miles from the Cauvery Falls. A scheme which promises to be the parallel of this one both in importance and scope is now projected for the West Coast of Africa, better known as the Gold Coast. In the absence of coal or other suitable fuel it is recognised that if electric power is to be utilised, it must be generated by water power. It is therefore proposed to harness the River Tano, the second largest and longest river on the Gold Coast. The electric power produced would be used for hauling, pumping, and crushing as well as for operating light railways. Some particulars of the scheme appear in our contemporary *West Africa*. The Tano River, we are told, possesses a fall of over 75ft. within a distance of one mile, the largest fall being considerably over 40ft. in a distance of 100 yards, and competent mining engineers are convinced that what is practicable in India is practicable in West Africa. There is, of course, the question of the distance of transmission, but it is not thought likely to prove an obstacle to the adoption of the present scheme. From the Cauvery Falls to the Kolar mines is over 92 miles, whereas the approximate distance from the Tano to the Tarkwa centre does not exceed 40 miles. At any rate it will be safe to place the total distance, including distributing lines, at about 60 miles, which in time could easily exceed 150 miles, sufficient to tap any of the colony's goldfields. The cost of a 5,000-h.p. transmission plant is roughly estimated at £140,000, the capital required for its erection at between £20 and £30 per effective horse-power, and the operating expenses, taking into consideration the local conditions, at £28,500. The output of such a plant operating on a mixed load 24 hours per diem for 300 days per annum would be, say, 21,480,000 kilowatt-hours per annum, which brings the net cost to less than 2d. per horse-power per hour. The writer says the cost of horse-power per annum of steam power generated by coal and wood fuel would in West Africa exceed £40. Therefore, in placing the average price of an electrical horse-power per annum at £25 for 5,000 h.p., the gross income would be £125,000, less working costs £30,000—total, £95,000 profit, or 25 per cent. on £300,000 nominal capital, with 6 per cent. per annum for the amortisation, which would allow the capital being paid off in 15 years. Over two dozen mines, it is said, are at least rapidly approaching to a stage when the necessity for a cheap power will become inevitable, and it is contended that if 20 odd companies are the only consumers available under the outlines of the scheme, they will benefit to an extent proportionately higher than the 11 Kolar mines, which are expected to save well over £50,000 in working expenses during the existence of their 10 years' contract. We gather from the article that a syndicate has been formed to develop the Tano River scheme.

A Graphic Recording Ammeter.—Before the American Institute of Electrical Engineers at the end of last month, Mr. A. H. Armstrong described in detail the construction of a graphic recording ammeter for use on electrical cars. It seems that a dynamometer construction is employed, in which the current to be measured is carried by the fixed element, and the moving element carries a constant current supplied preferably by a small storage battery. The moving coil is a small rectangle made up of several turns of wire, surrounding an iron core of cylindrical shape, carrying about one ampere. This coil and core are enclosed in the fixed coils. The moving coil is suspended by a control spring, and held in position by this spring at the top and by a small steel shaft at the bottom. The bottom bearing is so made that when in use the moving system hangs freely from the control spring, but its vertical motion is so limited that any excessive vibration cannot damage the instrument. Current is led into and out of the moving coil by two spiral conductors of negligible elasticity in comparison with the control spring. The latter is adjustable by changing its length. The ampere-turns in the fixed coil of the ammeter are about 2,400, the ampere-turns in the moving coil about 80, and by this combination a torque at the end of the scale of about 200 gramme-centimetres is secured. This is from 80 to 200 times the torque usually employed in measuring instruments in which the indications of a pointer on a scale are observed, and from 3 to 15 times that employed in the usual integrating or curve-drawing instruments. With this high torque the friction due to the pen moving over the paper is practically negligible. The pen used consists of a capillary tube supplied by a siphon filled from an ink reservoir carried some distance from the recording point toward the axis of the instrument. In testing with such instruments it is usual to employ at least two, an ammeter and a voltmeter, and in order that the line can be accurately marked on the paper a time-marking clock is employed. It is thus possible to obtain simultaneous readings by the instruments placed upon different cars in a train, a valuable feature where the different cars are each equipped with their own motive power. The recording instrument in this service is estimated to replace the labours of several men required by the old method of two-second readings, and gives results of greater accuracy. The following general data with which the author concludes the paper are of considerable interest: Length, 32½in.; width, 13½in.; height, 11¼in.; approximate weight, 100lb.; torque of ammeter, 210 gramme-centimetres (full scale 24deg.); torque of voltmeter, 200 gramme-centimetres; period, 0·33 second for complete cycle; ampere-turns in fixed coil of ammeter, 2,400; ampere-turns in fixed coil of voltmeter, 950; ampere-turns in moving coil of ammeter, 80; ampere-turns in moving coil of voltmeter, 189; watts consumed in moving coil of ammeter, 1; watts consumed in moving coil of voltmeter, 3·3; watts consumed in fixed coil of ammeter, 130; watts consumed in fixed coil of voltmeter, 33.

Electric Haulage on Canals.—What is practically the first example in America of employing electric haulage on canals has recently been put into operation in the case of the Miami and Erie Canal in Ohio. The total length of this waterway is 244 miles, and runs between Cincinnati and Toledo. The first section to be put into operation by electrical methods is that between Cincinnati and Dayton, a distance of about 68 miles. An excellent illustrated description of the installation is given in the current number of the *Street Railway Journal* by Mr. Chas. W. Ricker, from which we are able to gather the following main details. The work is of peculiar interest, both as constituting the first attempt at mechanical canal haulage in the States, and as the first serious application of three-phase traction motors on that side of the water. Briefly, the plan of operation is the haulage of tows of eight or ten canal boats by a locomotive running on a track beside the canal. So far this is in accordance with the present Continental practice. The locomotive, however, in this case uses three-phase motors, and takes current from a pair of trolley wires at high voltage, which is reduced by transformers on the locomotive itself. The transmission of power is necessarily over a long stretch, having regard to the length of the canal, and everything pointed to the use of high-voltage working conductors fed by a relatively small number of sub-stations, and feeding in their turn alternating-current motors upon the locomotives. Power for the section now in operation is taken from the lines of the Cincinnati Gas and Electric Company as a matter of convenience. The power, as 4,200-volt, 60-cycle, three phase current, is received in a motor-generator station, which changes the frequency to 25, and separates the haulage system from the local lighting and power system. Part of the output, at 390 volts, feeds directly the first section of working conductors. The remainder is stepped up to 33,000 volts, and transmitted along the canal bank. At four sub-stations transformers receive the 33,000-volt current and deliver it to the working conductors at 1,170 volts. The locomotive receives the current and transforms it to 390 volts for use in the motors. The principal interest in the system centres in the locomotive itself. This is of the compact type designed for mining work and weighs 55,000lb. It has four 33in. wheels mounted on 6in. axles with 5in. journals, and to each axle is geared with a double-speed reduction an 80-h.p. three-phase induction motor. The two motors are normally operated in tandem. The primary winding of the first motor is connected to the transformer secondaries, its secondary winding to the primary of the second motor, and the armature of this last is closed through a controller and a set of iron grid resistances. This controller serves for reversal and speed variation when required, although the motors in tandem are designed to give the 3 m.p.h. to which the speed is at present limited by statute. In this normal operation the motors give 40 h.p. each, and a horizontal effort with 25 per cent. coefficient of adhesion of 9,600lb. In view of the exceptionally large weight of the locomotive, specially heavy rails are used in the construction of the track, which, of course, is also of special design. Electric traction on canals has been proved on the Continent to be both feasible and practical, but it would be well to wait for authoritative figures of operation before the failure or success of the special system in question is discussed.

Institution of Electrical Engineers.—The attendance at the opening meeting of the new session of the Institution of Electrical Engineers on the night of the 12th inst. was quite worthy the occasion. Mr. Robert Kaye Gray, the president, was to deliver his inaugural address, and in anticipation of what was to be expected from an engineer of Mr. Gray's wide reputation and high status in the profession, the members came in their hundreds, so that every seat in the commodious lecture theatre at the Institution of Civil Engineers was occupied shortly after 8 o'clock. Mr. James Swinburne, the late president, sat on the left of Mr. Gray, and there were also present, among others, Sir Henry Mance, Profs. Ayrton, Perry, J. Grylls Adams, and S. P. Thompson, Mr. J. Gavey, Mr. Alex. Siemens, and Mr. J. W. Swan. The address which Mr. Gray delivered will long be remembered by the members for the masterly way in which it reviewed and described the progress

Digitized by Google

in the numerous fields of electrical engineering as they exist to-day, including electric lighting, electric traction, transmission of power, submarine and overland telegraphy, and electro-chemistry, but for nothing so much as the advice it contained for the future welfare of the Institution. Mr. Gray's references to a "temple of engineering" at Westminster were enthusiastically welcomed by the meeting, and the absorbing interest with which this question of providing a permanent home for the Institution is being met was well reflected in the later speeches of Prof. Ayrton and Mr. Gavey. The suggestion thrown out by Mr. Gray in favour of establishing a "London Section" on the same lines as the provincial local sections as distinguished from the parent body, and the reasons which he gave for advocating such a proposal, will be read with interest by those who were unable to attend the meeting. In accordance with custom, before Mr. Gray delivered his address the prizes and premiums awarded for papers read last session were distributed by Mr. Swinburne, under whose *régime* they were mostly gained. To Prof. Ayrton—lately returned from his tour in America as a member of the Education Committee—was assigned the pleasant duty of proposing a hearty vote of thanks to the President. He remarked that while singing the praises of electricity in this country, Mr. Gray had warned them that they ought to improve. They all joined with their President in his wish that Westminster might see the rising of a temple of engineering, but he feared that the history of that project would be the history of so many others. England organised the idea, America adopted and developed it, and then later on England reimported it. More than 20 years ago Sir Wm. Siemens proposed that there should be such a temple of engineering, and he was generous enough to offer to start the subscription list with a sum of £10,000. In New York, mainly through the generosity of Mr. Carnegie, there was to be provided a great hall for the use of four large engineering societies, and the land and money had already been provided. He supposed that later on England would import this idea with the privilege of paying a duty under the Chamberlain protection tariff. The reference of the President to submarine telegraphy was to him pathetic, for it brought back the image of many a past president, now dead, sitting in the chair—men who made England distinctly first in the manufacture and laying of submarine cables, and in which, thanks to such men as their President, this country was still first. He asked the meeting to extend to their President its best thanks for the instructive, interesting, and even amusing address he had given them. Mr. J. Gavey, in seconding the vote, recalled the time when the Institution was essentially a telegraph society, and when the electrical industry was practically comprised in the word telegraphy. Seeing that their President was one of the pioneers of submarine telegraphy, it was with the very greatest pleasure that they saw him occupying the presidential chair that night, and it was with the utmost pleasure that he seconded the resolution. Needless to say, it was carried by acclamation, and the President having briefly returned thanks, the meeting broke up.

City and Guilds Institute.—A very interesting, but in some respects disappointing, volume is the report just issued on the work of the department of technology of the City and Guilds of London Institute for the session 1902-3. It is signed by Mr. Wm. Bousfield, chairman of the Technology Committee, and Mr. Philip Magnus, the superintendent of the department, and provides an excellent insight into the progress which is being made in the teaching of technological subjects in London. In point of numbers a substantial advance is shown. The number of registered classes in technology has increased from 2,320 last year to 2,789 this year, and the number of students from 36,189 to 38,638. Glancing through the report our attention is arrested by the following sentence: "The large percentage of failures in all the preliminary examinations is an indication of the unprepared condition of the candidates on commencing their technological instruction." The unpreparedness of the students appears to lie chiefly in their inability to reduce their knowledge to expression, which seems to indicate that the standard of mental training in the preliminary schools is not a high one. It is obvious that students whose elementary education is defective cannot be expected to benefit by higher instruction in mathematics, science, or technical subjects. Passing on we come to the programme arranged for the present session, and find that in telegraphy and telephony and electric light and power the syllabuses have been revised, in order, presumably, to keep pace with the times. Further, the former syllabus of examination in electro-plating and deposition has been replaced by an extended syllabus covering electro-metallurgy, including electrolytic refining, electric smelting, and electro-plating. After the general report are given a number of tables of statistics, followed by a collection of extracts from some of the examiners' reports on the results of the last examinations. With regard to telegraphy and telephony, the rather laconic remark at the end of the report is that "on the whole the standard of work is about the average." This, however, cannot be regarded as a very satisfactory state of things in view of what the examiner has to say about the general capabilities of the students. Even the best informed of the candidates, it seems, can rarely deal satisfactorily with more than six of the eight selected questions, and very simple calculations are quite beyond the capacity of the average student. Generally speaking, even the most simple questions are very feebly dealt with, and the examiner notes with dissatisfaction that, as a rule, the honours candidates are little, if at all, in advance of the ordinary in the quality of their work. In electric lighting and transmission of power there has been an increase in the number of candidates, especially in wiremen's work, where the increase is nearly 80 per cent. The examiner reveals a more satisfactory state of things in regard to this subject than in telegraphy. Some of the papers at the last examination were exceptionally well done. A marked difference was noticeable, however, between the answers to questions relating to direct currents and those dealing with alternating currents, the answers to the former being very much better than to the latter. In the honours grade none of the papers sent in were sufficiently meritorious to warrant the recommendation of any first prizes. The average quality of the wiremen's work was not so good as last year, less skill being shown in making metal joints, etc. Insufficient attention was paid to effective insulation in the majority of cases, many of the candidates using prepared tape as an insulator instead of as a mechanical protection only. The chief defects in the work may be enumerated as follows: tape left on original rubber between metal and braiding, length of original rubber between metal and braiding insufficient, new rubber not extended far enough over original rubber, too much solution used, want of cleanliness, original rubber cut through in removing braiding, etc. As regards electro-plating and deposition the work at this year's examinations was inferior to that done last year; there was no pre-eminently good paper in either grade, and the average was anything but satisfactory. This result is all the more disappointing after the very marked improvement shown in the papers submitted by candidates last year.

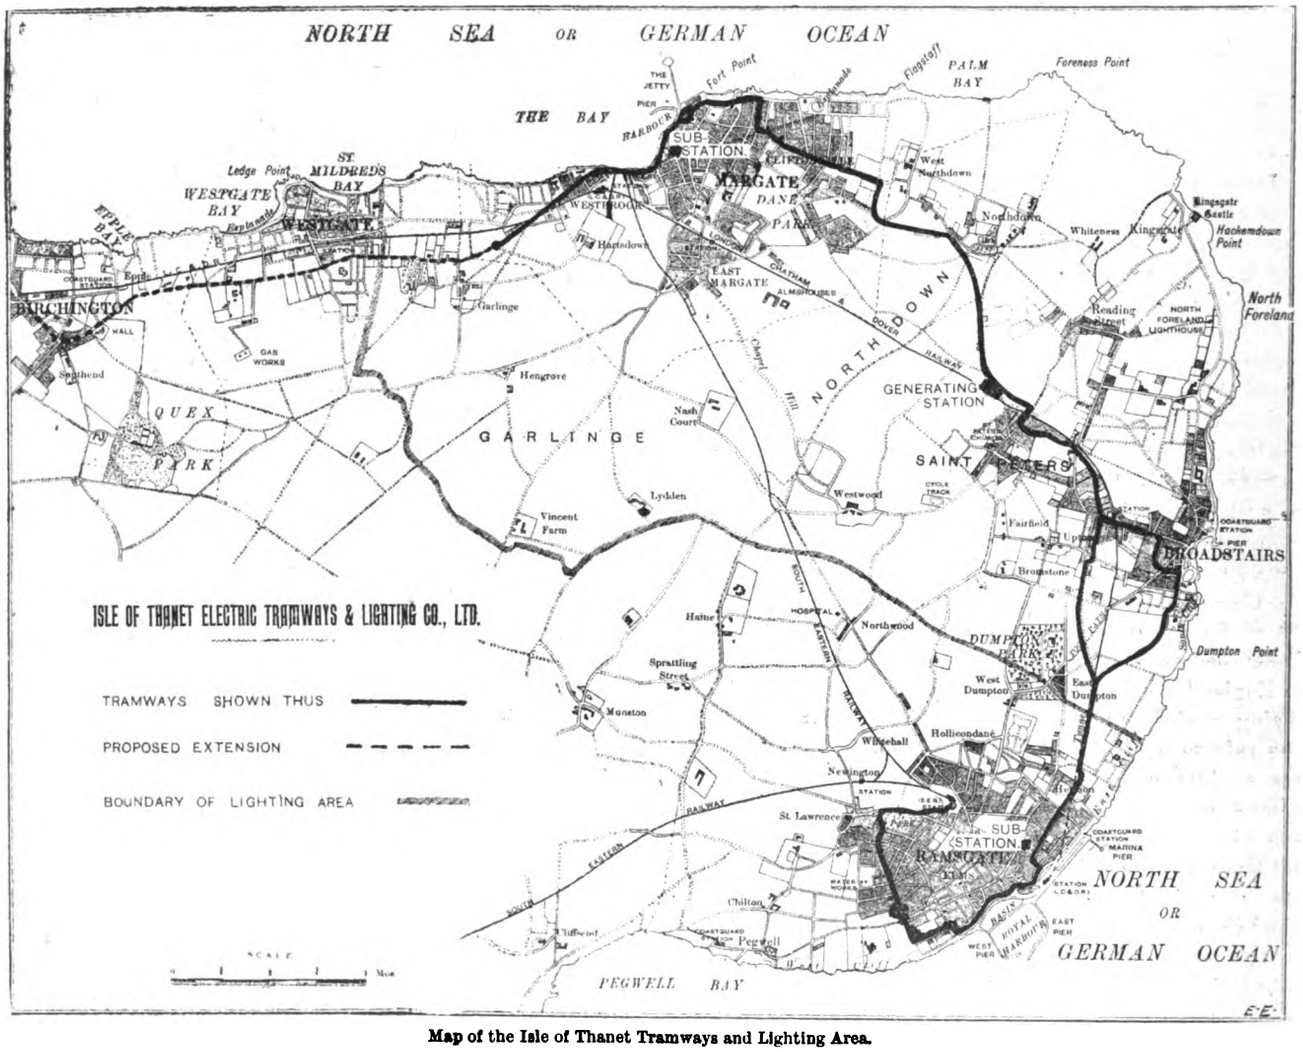
ISLE OF THANET ELECTRIC TRAMWAYS AND LIGHTING COMPANY.

BY B. PONTIFEX.

The Isle of Thanet tramways form an excellent illustration of the best sphere of usefulness for a service operated by one controlling authority. There are several boroughs in the island, but none of them is sufficiently powerful to absorb the remainder and provide municipal control for any common scheme, which is, consequently, best carried out by an independent company. For example, at present three boroughs, together with some outlying parishes, are traversed by the tramlines. What confusion and inconvenience would be caused if, supposing the lines were run by the separate borough councils, one of those councils withdrew its portion of the route from service during the winter season, when traffic is barely sufficient to clear running expenses? This is quite apart from any consideration of economy in the cost of generating power for the line, which naturally works out more cheaply with one big station than with three small ones.

The company operating this light railway was formed by Mr. W. M. Murphy, to whom the Commissioners of Light Railways granted an order in December, 1897, which was confirmed by the Board of Trade in August, 1898. The local authorities concerned have the right to purchase the undertaking after a period of 42 years, but compulsory acquisition cannot be enforced unless two-thirds of the Councils of Ramsgate, Margate, and Broadstairs agree to the terms of sale. The local improvements which have been carried out by the company include over three miles of new road, while nearly another two miles of highway have had to be reconstructed, with the result that large areas of new land along the Foreland cliffs has been made available for building purposes and are being rapidly occupied. The consulting engineers for the scheme were Messrs. Kincaid, Waller, and Manville for the construction work, and H. F. Parshall, Esq., for the electrical equipment.

At present the tram route extends from Garlinge, a short distance from Westgate, through Margate, along the sea-front to Cliftonville, thence to St. Peter's (where the power station has been built), passing on through Broadstairs to the sea-front at Ramsgate. After passing Ramsgate Harbour the line turns sharply to the right to the present terminus at the S.E.R. Station. There is also a loop line at Broadstairs, which passes under the railway to the sea-front and rejoins the main route at Dumpton. The construction of this loop line necessitated the building of a new railway bridge without interrupting traffic, and lowering the roadway to enable the cars to clear the bridge with safety to outside passengers. The lines, as a whole, are fairly level, but what gradients there are make up for this by their steepness, as there are a few of 1 in 18, and also a length of 100ft. of 1 in 11, which is the maximum (quite enough, too!). The curves generally are easy, but some are, unavoidably, of short radius, the worst



Map of the Isle of Thanet Tramways and Lighting Area.

of these being 40ft. An awkward feature with the narrow gauge in use (3ft. 6in.) is the extreme amount of "overbang" of the car bodies when rounding curves, which has caused much trouble with new drivers when the streets are crowded with other traffic in the summer.

Since the line serves a district which relies entirely on "holiday" attractions, there is naturally an enormous difference between the summer and winter costs and revenue; in winter 14 cars run with 15 minutes interval, but in summer a service of 56 cars is maintained. The results are shown by the following table of costs:

Expenses per Car Mile, in Pence.

	Winter, 1902-3.	Summer, 1903.	Average.
Power	2·16	1·35	1·75
Maintenance	1·16	0·67	0 91
Traffic	2·27	2·20	2·23
General and management	0·76	0·29	0·52
Total	6·35	4·51	5·41

From April 4, 1901, to Sept. 30, 1902, which completed

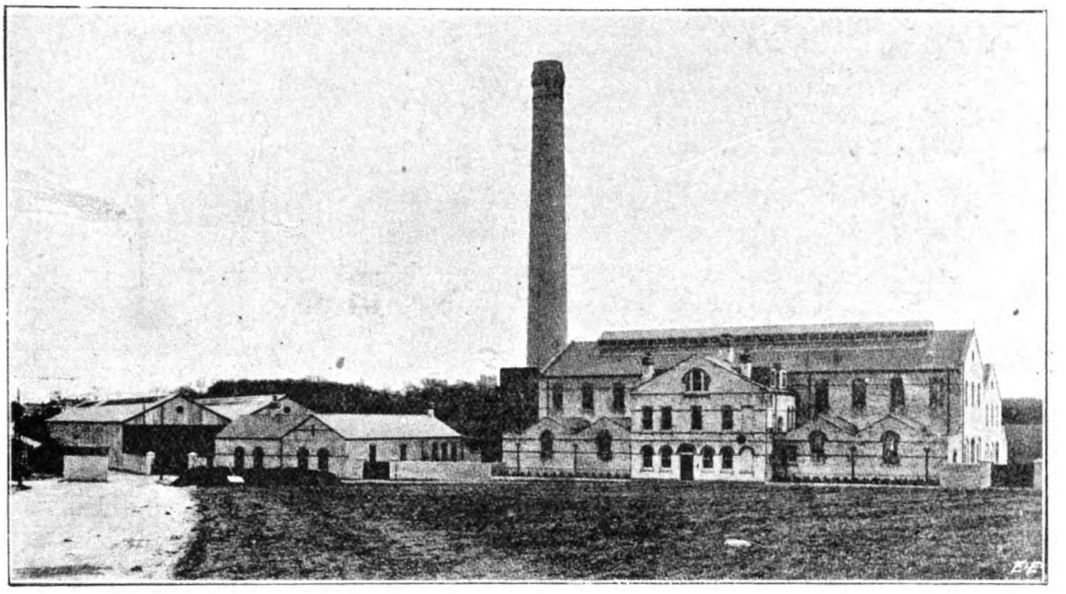
Digitized by Google

the first 18 months of working, the following results were obtained:

Traffic.—Miles run	1,324	790	
Passengers	7,500,245		
Units used	2,008,208		
Expenses.—General	£20,689	8	8
Power	10,680	8	4
Maintenance	5,019	2	8
Receipts.—Traffic	60,298	19	5
Lighting	128	19	5

the other at Margate, an arrangement which is enforced both by the length of track and by the existence of electric lighting orders. The generating plant consists of two 200-kw. direct-current generators and two 300-kw. three-phase alternating-current generators, two Tudor batteries, and a rotary converter. The sub-station plant consists of 100-kw. rotaries with static transformers, and Margate sub-station also has a Tudor battery.

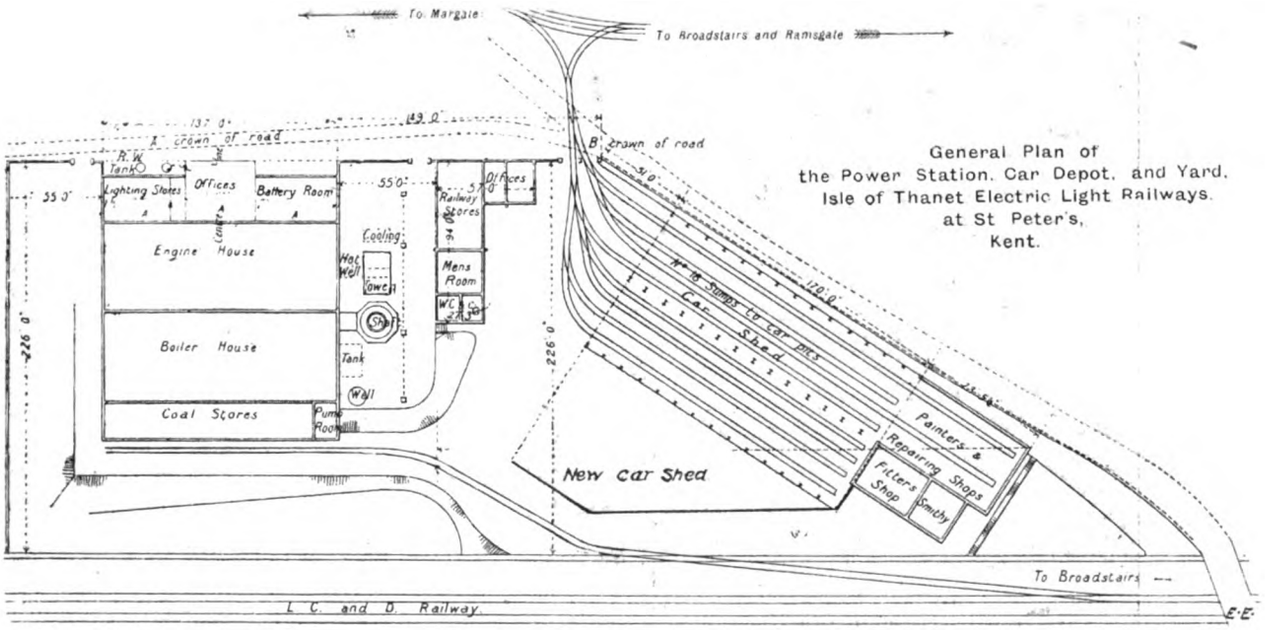
The generating station is built of yellow brick, made locally, and the boiler and engine houses are each 134ft.



A General View of the Isle of Thanet Power Station and Car Sheds.

Extensions of the line are contemplated through Westgate to Birchington, while the lighting of these towns has also been undertaken. At present the electric lighting provisional orders for Margate and Broadstairs have been taken over, and supply is being given in these towns from sub-stations described below as fast as the necessary mains can be laid, while 25 arc lamps are supplied in Broadstairs for public street-lighting.

by 50ft. in area. There is a coal store, 20ft. in width, along the back of the boiler-house, where the private siding is brought up so that coal can be discharged from the trucks straight into the store. In the boiler-house are four Babcock and Wilcox water-tube boilers, arranged two in a battery, with space to instal four more; they are worked at 160lb. per square inch, and have each 3,140 square feet heating surface. They are hand-fired—in fact,

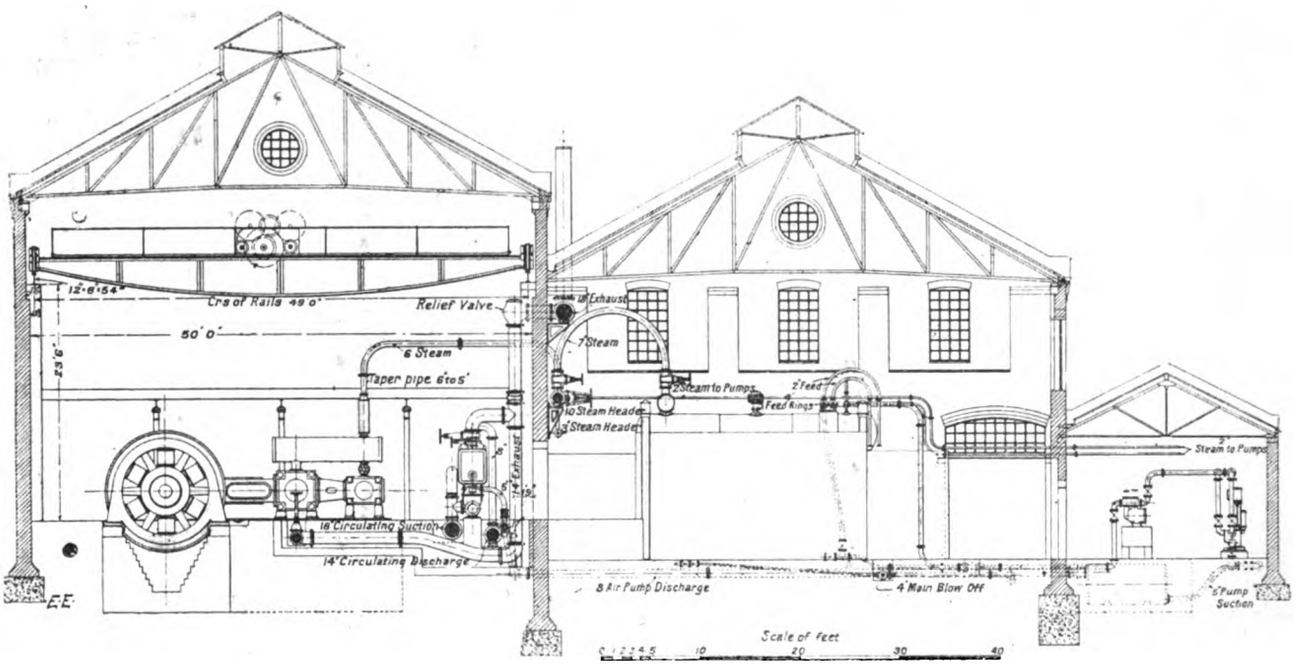


Power-House.—This is placed near the middle of the line in the parish of St. Peter's, Broadstairs, and is connected with the Chatham and Dover Railway by a private siding, but, as an alternative, a track has been laid on the quay at Ramsgate Harbour, and material and supplies can be brought over the company's own line from ship to the power-house—a rod in pickle which should ensure prompt delivery even from our old friend the Chatham and Dover Railway. The track is fed directly from the generating station and from two sub-stations, one at Ramsgate and

there is no mechanical coal-handling anywhere in the power station. The feed piping is duplicate throughout, while the steam-pipes are laid on the single header system with section stop-valves. All expansion is taken up by large U-bends. The pipes are of lap-welded mild steel, with flanges screwed on to the ends, which are afterwards expanded. There is an economiser of 240 tubes in two sections, made by the Claycross Company, with scrapers driven by belt from a small engine. The chimney shaft is 162ft. high with 8ft. 6in. internal diameter.

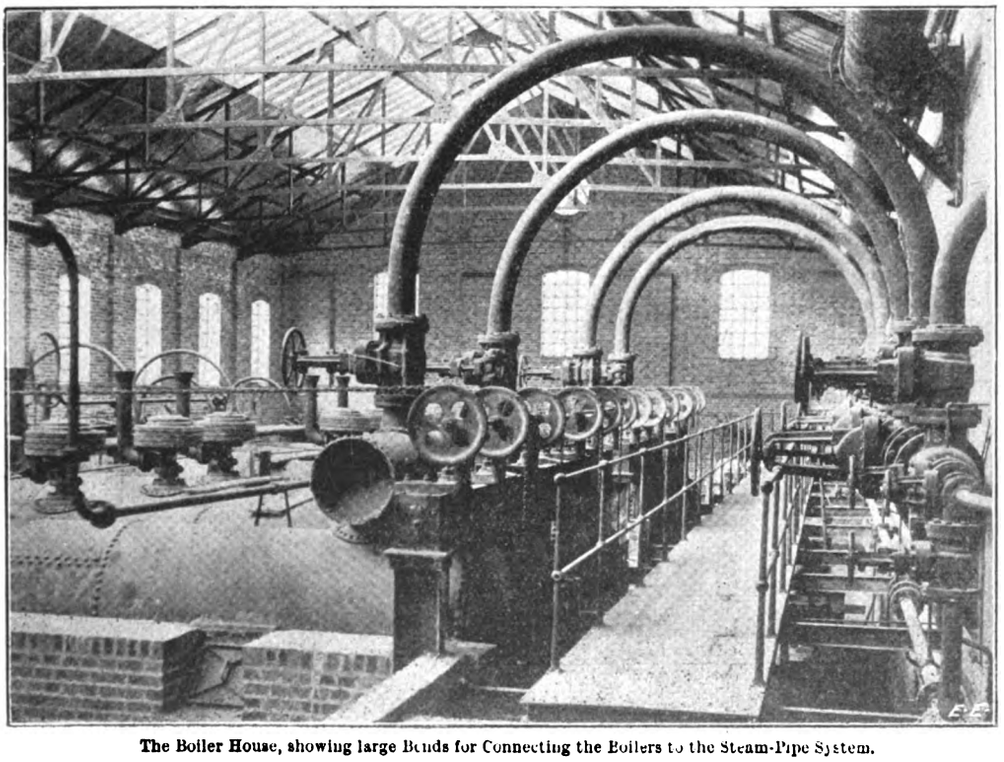
Digitized by Google

The pump-room contains two Blake-Knowles vertical, duplex, ram feed pumps, capable of delivering 4,000 gallons of water per hour with a piston speed of 50ft. per minute. Railton and Campbell filters are installed to deal with impurities in the feed water—mostly oil when the hot-well is in use. The feed water is taken from a storage tank outside the boiler-house, which is supplied from a well 180ft. deep by a Worthington deep-well steam-pump with a total lift of 150ft. The same pump supplies the making up water for the condensing system. Since the water comes from the chalk, a water softener is a necessity, and one has been erected by the Desrumaux Water Softener and Purifier, Limited, of Bradford, to deal with this. In emergency there is an alternative supply from the water company's mains.



Cross Section of Engine, Boiler, and Pump Rooms, Showing General Arrangement of Pipes.

In the engine-room there are two three-crank tandem compound vertical enclosed engines by Messrs. Belliss and Morcom, running at 300 revolutions per minute, with a steam pressure of 150lb. per square inch. It was laid down that the speed should not vary more than 1½ per cent. from normal, consequently the flywheels are heavier than usual. Direct-coupled to each engine is a British Thomson-Houston three-phase generator with stationary armature, the fields being excited from the 500-volt direct-current 'bus bars. Iron collector rings and carbon brushes are used. The machines develop 300 kw. at 2,500 volts, and have 20 poles, which at normal speed gives a frequency of 50 cycles per second. There are also two single-crank, tandem, compound, horizontal Allis engines of 320 i.h.p, running at a normal speed of 135 revolutions per minute under 150lb. pressure. The cylinders are 14in. and 28in. with a 30in. stroke, and the intermediate receivers are jacketed with live steam at



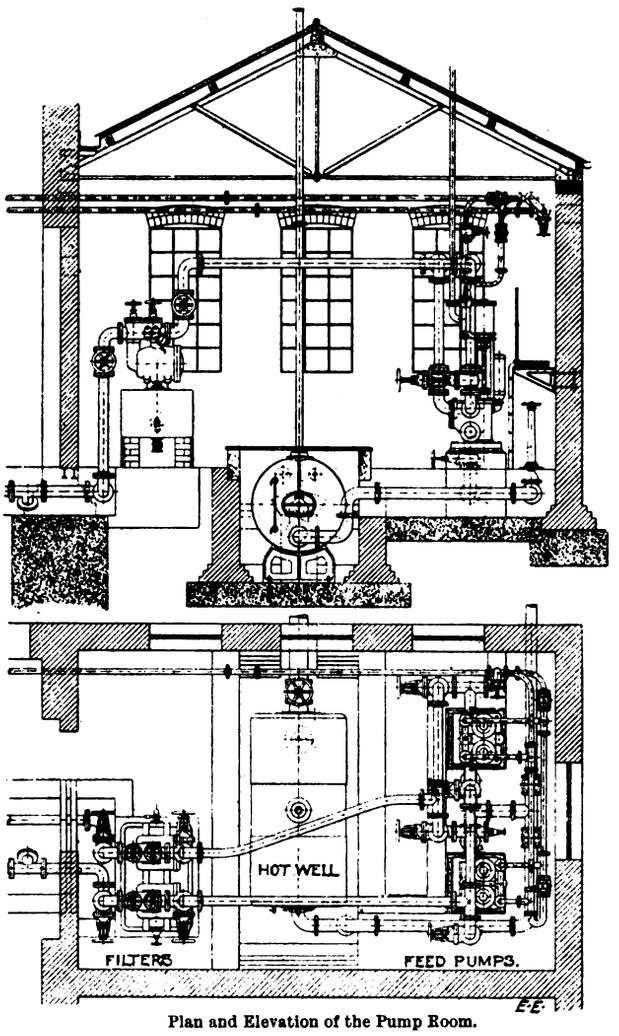
The Boiler House, showing large Bends for Connecting the Boilers to the Steam-Pipe System.

boiler pressure. An expansion governor is fitted which regulates the cut-off in both high and low pressure cylinders. The valve gear is the Reynolds-Corliss pattern with vacuum dashpots. These engines are allowed 2½ per cent. speed variation; while the more powerful British engines are only allowed 1½ per cent. The direct-current generators coupled to these are by the

Digitized by Google

General Electric Company, U.S.A., and are designed to work as shunt machines on the lighting circuit and compound wound on tram work. The output of each is 200 kw. at 500 volts at normal speed; they are six-pole machines with drum armatures.

The condenser plant consists of three Wheeler standard pattern surface condensers, with compound steam circulating and air pumps mounted under the condensers, which have



Plan and Elevation of the Pump Room.

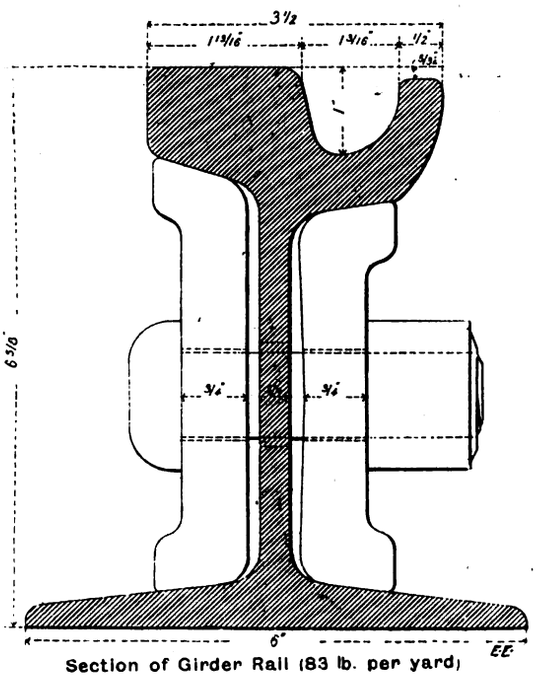
each 1,300 square feet cooling surface. There is also one of their cooling towers fitted with two sets of fans, each driven by a motor in the engine-room.

There is one 100-kw. rotary converter with three static transformers and regulator for use, in conjunction with the batteries, on the Broadstairs lighting, which is supplied from the power-house.

The battery consists of two sets of 265 Tudor cells with a capacity of 280 ampere-hours, if discharged to a minimum voltage of 490 with a maximum discharge rate of 72 amperes. The maximum charge rate is 40 amperes. They are of the central-station type, L A pattern, in lead boxes, nine plates in a cell. These batteries are charged by the aid of positive boosters.

The switchboard, of enamelled slate, is carried on a gallery at the end of the engine-room. It is divided into sections for the high-tension three-phase current, traction circuits, and lighting and battery circuits. There are separate panels for each generator, the boosters, balancer, and high and low tension feeders. The high-tension switches are of British Thomson-Houston long-break pattern, and there are also some of their oil-break switches fitted, one in particular being arranged to separate the high-tension 'bus bars so that Margate and Ramsgate sub-stations can be fed from separate generators.

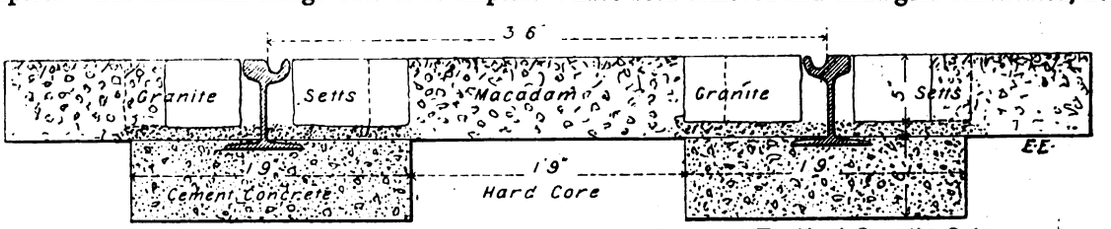
The high-pressure three-core, paper-insulated cables run each way, two to Margate and two to Ramsgate to supply the sub-stations. They are laid solid, and are manufactured by the British Insulated Wire Company. The cross-section is ·05 square inch. The traction feeder cables are supplied by the same firm and are laid in the same way. These are ·2 square inch in section, and are laid in either direction from the power-house to within about half a mile from the termini.



Section of Girder Rail (83 lb. per yard)

The lighting cables are triple-concentric supplied by Callender's Cable Company and are laid solid; the feeders are ·5 square inch and distributors ·1 square inch section. These are laid in Margate and Broadstairs only, since electric lighting has not yet been developed in other parts of the district. The three-wire system is in use with 480 volts across the outers.

Sub-Stations.—At Margate sub-station there are two 100-kw. eight-pole rotary converters by the British Thomson-Houston Company, with room for two more. These machines are supplied with low-tension alternating current at 310 volts from oil-cooled static transformers, and in their turn supply at 500 volts to the traction feeders or lighting switchboard as required. There is accommodation for six more static transformers when the extra rotaries are put in position. Automatic regulators worked by small three-phase motors are in use for keeping the alternating-current pressure constant, but the motors have been removed and hand-gear substituted, not because they failed, but because they were too sensitive. The lighting board is separated from the traction board entirely, and it will be worth while to study the booster connections on the switchboard diagram because the booster is reversible, and if necessary all the cells can be discharged with the booster working against them to keep the voltage at the declared pressure at consumers' terminals. The battery regulating switches are of the screw type worked by hand. The battery is of the same pattern as those at the power-



Section of Permanent Way (Single Track) with Macadam and Toothed Granite Sets.

Digitized by Google

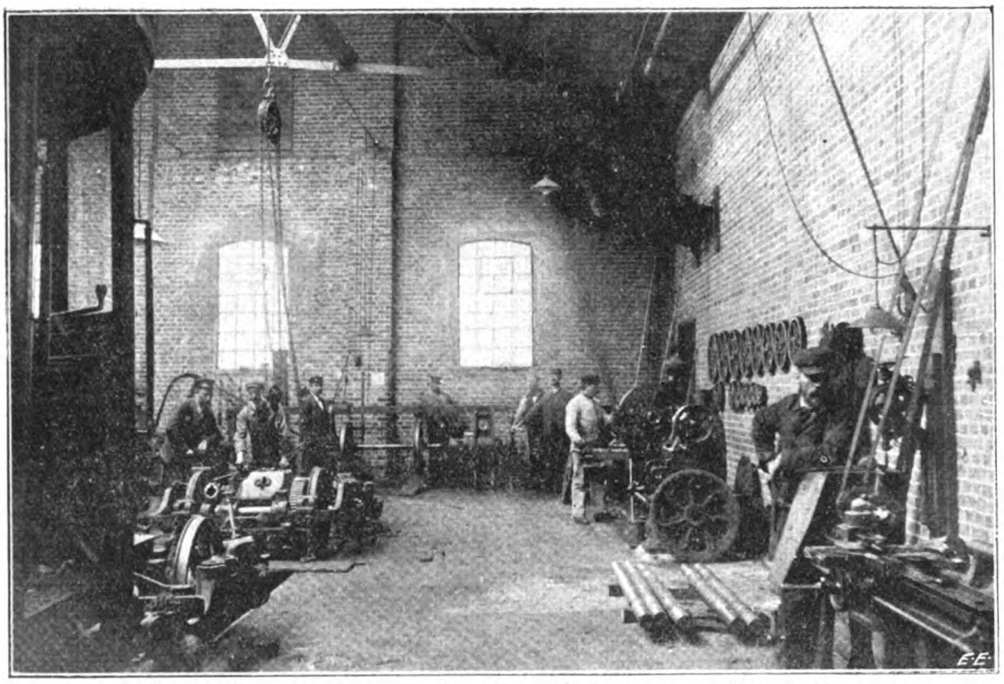
house, but with a capacity of 420 ampere-hours with a maximum discharge of 108 amperes. At Ramsgate sub-station there are three 100-kw. rotary converters with nine static transformers, all of the same size and pattern as the Margate machines, but there is no lighting load and no battery.

Permanent Way.—There are 10 miles of double track and one mile of single. The gauge is 3ft. 6in. laid with girder rails which weigh 83lb. per yard. They were supplied by the Lorain Steel Company in 30ft. lengths; the groove is $1\frac{3}{16}$in. wide and 1in. deep, while the rail is $6\frac{5}{8}$in. deep with a 6in. base. The fishplates are of the usual pattern, and the bolts are held by Helicoid lock-nuts, which are reported to be holding well against vibration and jars. Through the towns the track is paved with jarrah laid on 6in. of cement concrete extending 18in. each side of the track. Between towns macadam is used between the rails, which have granite setts on each side; concrete is in that case laid 1ft. 9in. by 6in. deep under each rail. All points are of crucible cast steel, supplied by Messrs. Askham Bros. and Wilson, of Sheffield. Double bonding is carried out at every joint, bonds being 6/0 L.S.G., while cross bonds of the same gauge are fixed every 120ft. The trolley standards are planted at 40 yards intervals; they are 30ft. long and weigh 990lb. Side arms are used over nearly all the route, except along the parade at Margate, where centre poles have been adopted. The trolley wire is double throughout, suspended over the centres of the tracks; the gauge is 00 L.S.G., and the breaking strain is 4,500lb. Flexible suspension is not used; the hangers can swing from the bracket arms, but there is no up-and-down motion possible, but, of course, it is not so material on a line where speed is cramped by considerations of stability due to the narrowness of the gauge. Section insulators are fitted every half mile, with the necessary feeder boxes and cables, etc.

Rolling-Stock.—The company possesses 60 cars in all, made by various firms—namely, 20 bogie cars (with pony wheels leading) and 20 single-truck cars with 35-h.p. motors, G.E. 58, and B.T.H. controllers, manufactured by the St. Louis Car Company, U.S.A.; 10 single-truck cars, by Messrs. Milnes and Co, and 10 by the British Electric Car Company, with Brill underframes. All these cars have enclosed vestibule ends and top seats, with the trolley standard in the centre line of the cars, and are fitted with hand-power track-brakes. The St. Louis cars have cast-steel side frames on the trucks.

The car-shed is situated at the generating station, and is 230ft. in length, with ample accommodation for all the cars, with pits running the full length of each track. The painting and repair shops open out of it. There is a small additional car-shed at Garlinge for convenience in saving long journeys when starting up in the morning and when closing the service at night.

I must express my thanks to Mr. J. Barber Glenn, the secretary of the company, and to Mr. R. Humphries, the resident engineer, for their kind assistance in the preparation of this article.



A Corner in the Repairing Shop of the Isle of Thanet Electric Tramways and Lighting Company.

INDEPENDENT TELEPHONY IN GREAT BRITAIN.

BY GARDNER AND HOLME.

(Continued from page 719.)

(5) Underground Construction.

The underground construction, including excavating and laying of pipes, building manholes and brick boxes, drawing in, jointing, and numbering cable, is best done by the corporation's staff or local contractors under the direct supervision of a capable resident engineer, as the persons doing the work are afterwards responsible for the maintenance of the system, and consequently good construction is ensured. The position of the exchange being decided upon, it is of great importance to select a building suitable for such a purpose; in the past little attention was generally given to the ultimate requirements of an exchange, some building being taken which in a short time proved totally unsuitable.

The buildings should be laid out as follows: the basement for the reception of the main cables; the first floor for office, stores, battery, power plant, test and distributing rooms; the second floor for operating and operators' cloak and retiring rooms. The arrangements of the rooms being laid out, all builders' and joiners' work should be completed before any of the apparatus or cables are installed. A brick or laced iron shaft of ample dimensions should be built for the reception of the main cables, from the basement to the test and distributing rooms, where angled iron frames and distributing racks are fitted ready for their termination. From these frames suitable conduits should be laid out and prepared ready to receive the switchboard cables from these frames to the switchboard. In the designing out of the Portsmouth exchange these details were all arranged for before any of the electrical equipment was installed.

The system to be adopted being decided upon and the number of lines for installation known (this is generally obtained from the result of an active canvass of the towns in the alloted area), it is well to plot out the obtained subscribers' lines in groups or blocks on a large scale plan of the town. From this plan the general distribution of the cables, number of pairs of wires in each cable, the

Digitized by Google

number of spares which should be allowed for, and the position and number of the distributing poles will be arrived at. Tracings should be prepared in the form of a diagram, as shown in Fig. 21, giving all details as to the conduits, position and size of each manhole, draw-in and junction box, the length and number of pairs in each run of cable and sizes, the number of through and T-joints, and the position and length of each sub-main and distributing cable. This system adopted, there will be no difficulty in checking the progress of the work, and in arriving at the exact lengths of cable to order forward in each case. It is also a great help in the checking of the contractor and in balancing the schedule of quantities.

shown in Fig. 23. From these cable potheads the wires are run overhead or inside the buildings to the various subscribers' offices. Joint-boxes should be arranged for throughout all the cable runs about every 180 yards in order to facilitate the handling and drawing in of the cables. The manholes and joint-boxes should be built with Staffordshire brindle brick or a good local brick on a flooring of cement and concrete, and bellmouths for the termination of the pipes built into the sides. They should be roofed in with covers, supported on steel joists capable of taking the strain of the road traffic. All conduits should be laid from 18in. to 2ft. under the surface, and cast-iron pipes used for the reception of the main cables. The best

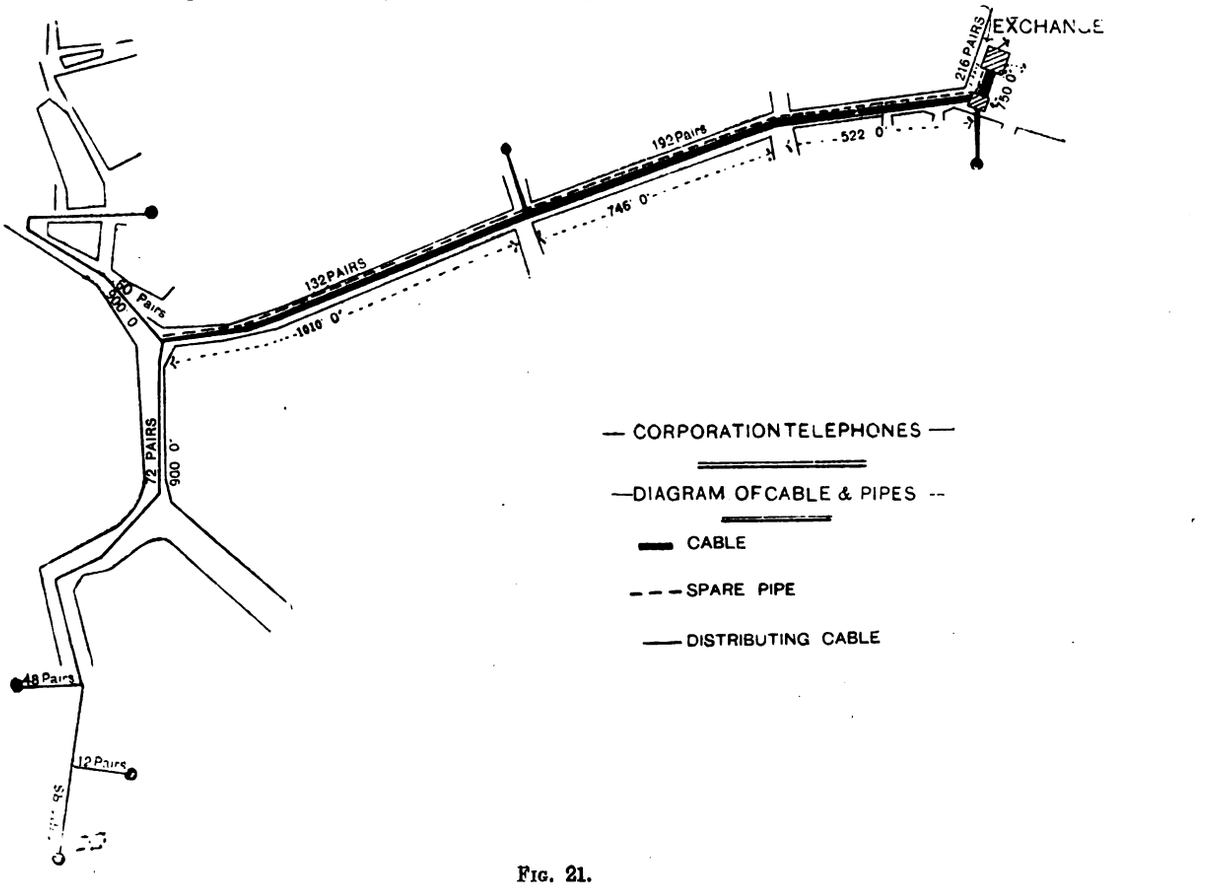


FIG. 21.

The scheme having been laid out and the position of the cable shaft decided upon, an underground passage should be built from the shaft to the main cable chamber in the street. This should be of sufficient size to admit of the cables being easily handled and examined, and be built of Staffordshire brindle brick with ventilating cover. From

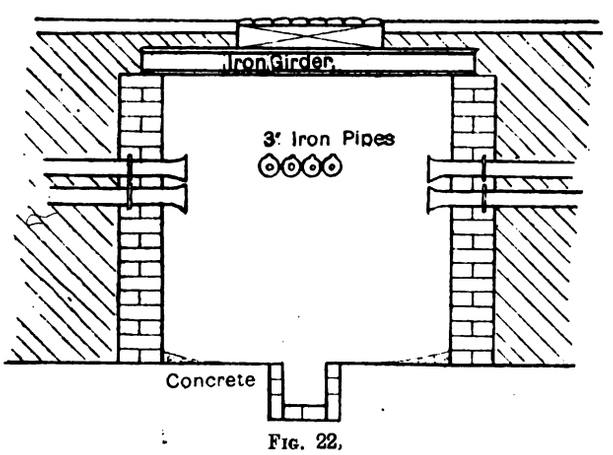

FIG. 22.

this chamber the main cables radiate in all directions to manholes; as shown in Fig. 22, placed in the main streets, from whence the sub-mains are taken through joint-boxes to the several distributing points. From these points armoured cable is laid in specially prepared creosoted wood troughings or conduits to the distributing potheads on poles or in large buildings. A pothead on a building is

pipes for main cables are the ordinary 9ft. cast-iron spigot and sockets, 4in. internal diameter, coated with Angus Smith's compound, and jointed with spun yarn and caulked lead so as to be thoroughly gas and water tight. Terminations in manholes should be made, as already mentioned, by bellmouths with cross connecting lug, as shown in Fig. 24.

The sub-main conduits may be either cast iron or earthenware pipes 2½in. or 3in. internal diameter. Some good three-way earthenware conduits are made, and if well and truly laid and bedded in cement mortar upon a foundation of concrete, and afterwards surrounded with concrete, are very suitable. For armoured distributing cables creosoted wood troughing, consisting of ploughed quartering laid together so as to form a 3in. conduit, and bound with soft-iron tape and the joints lapped, forms an excellent conduit. Comment has been made regarding the use of creosoted wood for conduits, but if a good quality of creosote oil is used no fear need be anticipated. As conduits are laid, a draw wire should be threaded in for use when pulling in the cables. This is of great importance, as it is an expensive matter to have to rod the conduits.

All conduits between boxes should be laid as straight as possible, so as to facilitate drawing in the cable, as a sharp bend puts an enormous strain on a telephone cable (which is entirely different to power or light cables), and ultimately the cable or rope will break, necessitating heavy expense in digging out. As the conduits are laid, wood plugs should be inserted in the ends whenever the work is left, so as to prevent stones or foreign matter entering the pipes. As the work is in progress, careful measurements and details should be entered in a book and drawings kept.

Digitized by Google

From these actual measurements the cables are ordered forward, about three yards being added on for jointing and spare end for drawing in. On arrival of the cable, the drawing in, jointing, and numbering is then proceeded with. The drums of cable as they arrive should bear the number of the test certificate, lengths in yards, number of pairs, size of conductors, and class of cables. This being done, it will be an easy matter to organise the drawing in without error.

Proceeding with the drawing in, here the importance of having the draw wire in the pipes will show itself. This wire is securely fastened to a chain, or better to a $\frac{5}{8}$in. steel-strand flexible rope, and drawn through to the manhole, where the cable is ready on the drum waiting to be pulled in. Before drawing in the cable, the ends should be examined to see the lead sheath is thoroughly watertight and sealed up. To fasten the steel wire or chain to the cable many devices have been tried. The best practice is to prepare the cable end by employing a practical jointer's plumber to fit a cable clip provided with swivel and ring for attachment to the steel-strand flexible rope or chain. To pull through a large cable requires power and care in handling, and should not be attempted without proper

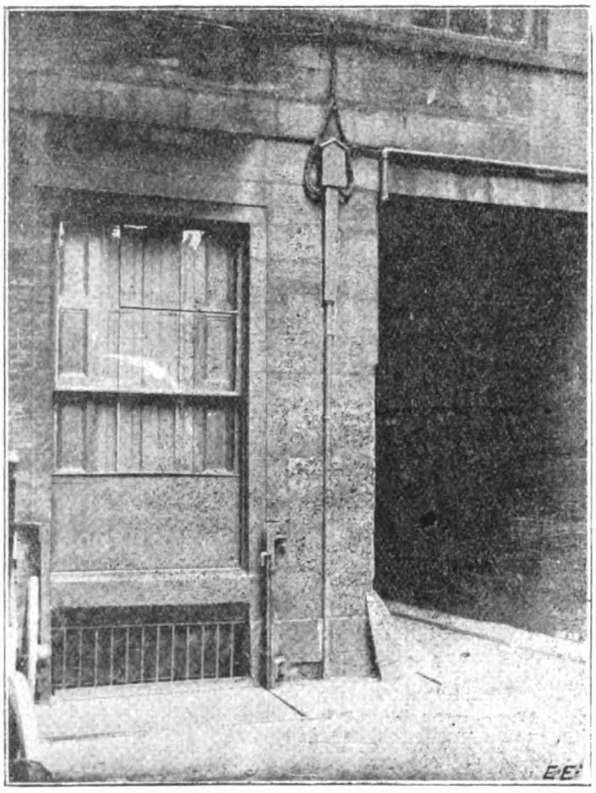

Fig. 23.

tackle. A good strong winch should be used, securely fastened down with weights or bars to the ground, the cable drum being set up near to the entrance to the manhole, and in such a manner that the cable will pay itself off from the top of the drum and pass through the manhole into the pipes without obstruction. Care should be exercised in assisting the cable entering the pipes, and plenty of good lubricant used, petroleum jelly being the best, as it gives a good body, and is free from any injurious substances. Cables in passing through boxes should be supported, and on the completion of the drawing in of each length, sufficient should be left for the purpose of jointing. The ends of the cable under no circumstance should be allowed to hang down, but be supported in case of fracture of the lead. Fractures of the lead happen if the cable is allowed to hang down, and as the fracture is generally several inches in the pipes, it does not show itself until long afterwards. The centre of the box should be kept clear and accessible for jointing by arranging the drawing in of the cables in proper order, and supporting them at the sides.

When the cables are laid the jointing of the wires is proceeded with, and the following description of the method of making a through joint applies to all the paper-insulated cables: (1) Place a tent over the joint-box where the joint is to be made. (2) Thoroughly clean the lead sheath with oil and waste. (3) Then, with a plumber's knife and hammer, take off the lead covering (leaving 3in. of lead on each side), care being exercised so that the insulation is not damaged. (4) The braid or tape to be stripped to within 1in. of the lead on each cable. (5) Bind round several turns of 1in. selvedge tape under the edge of lead so as to ensure the lead not damaging the wires. (6) Tie back on to the cable the outer layers of wires. Great care must be

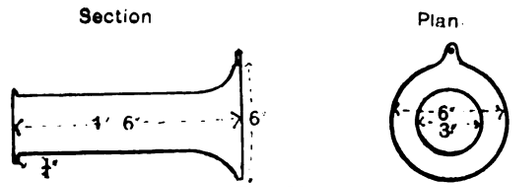

Fig. 24.

taken to see that each pair of wires are well twisted together, and also that each wire has its corresponding wire in the pair. Care should also be taken to see that the pairs are not crossed: the crossing of the wires sets up self-induction, which gives rise to "cross talk." (7) Tie back other layers or flakes in a similar way, putting a layer of tape round each flake. This will keep the layers or flakes from getting intermixed. (8) Bring the two pilot wires of the centre flake together. Strip off the insulation of these two wires and pass a paper sleeve over one of the wires to be jointed. (9) The ends are now tightly and evenly twisted together for a length of $\frac{3}{4}$in. at right angles to their length. Solder for a distance of $\frac{1}{2}$in., using patent solder. If the whole length of the twist was soldered, it would tend to make the copper wire brittle. Care should be taken when soldering to see that the iron is sufficiently hot, so as to ensure that the solder will properly take on the wire; if the iron is not hot the solder will not take, but only the resin: this will cause a fault of high resistance to be set up, thereby throwing the circuit out of balance. See that no loose solder is allowed to drop on to the underneath flake, as this is liable to cause a cross-contact fault. (10) Bend the twist parallel to its own length, care being taken that the wire is not nicked by the pliers. (11) See that the paper covering comes well up to the twisted copper. (12) Draw up the paper sleeve, so as to quite cover the twist. These joints should not all come together, but should be alternated so as to keep the circumference of the cable as small, and even as possible. (13) Tape binders or snuggers are to be taken off as each flake is finished. (14) Each flake is to be lightly bound with one coat of $1\frac{1}{2}$in. selvedge tape, edge to edge. (15) The joint should be thoroughly dried at intervals to get rid of any moisture absorbed while it is being made, the frequency of the drying depending upon climatic conditions. (16) Bring the wires to be jointed over those already jointed, and lightly tie them down, then take a sheet of stiff brown paper and cover over the joint. Bore a few holes in the paper, then place two lighted blow-lamps under the joint, so that the

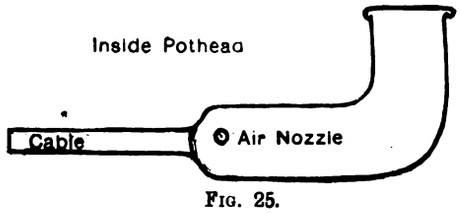

Fig. 25.

whole of the heat plays on joint, the distance of the lamps from joint being 18in. Care should be taken that no dampness arises from the ground under the joint. This can be obviated by laying down several layers of felt or other material. When all the pairs of wires are jointed up, a final drying-out should be given; the paper sleeves should be quite stiff, and the paper insulation quite crisp. (17) The joint is to be then wrapped round with one lapping of $1\frac{1}{2}$in. selvedge tape. (18) The joint is now ready for the plumber to wipe on the lead sleeve, which in the case of an armoured cable will be a split sleeve wiped longitudinally,

Digitized by Google

as well as at the two ends. When there is no armouring a lead sleeve should be slipped over the lead on one side before jointing, this doing away with the longitudinal wipe, involving, as it does, greater mechanical skill and more labour.

It is absolutely essential that all joints in the lead covering be perfectly air-tight and no moisture allowed to enter. After the joint is wiped an airtight nozzle is fixed 3in. from the end of the wipe. Air is then pumped in by a small hand-pump through a drying cylinder. This will help to dry the joint, and also show if the wiped joint is sound. Any local escape of air will be noticeable by putting soft soap round the wipes. The construction of a T-joint where two small cables branch from one larger one is practically the same as for a straight-through, with the exception of the lead sleeves. The ultimate termination of the cables is in pothead joints, where the paper-insulated cables are jointed to the vulcanised indiarubber-covered wires for distributing to the subscriber's premises either inside large buildings or overhead from poles, and the following points should be observed: (1) A lead sleeve should be slipped over the vulcanised-indiarubber, lead-covered cable, the diameter of the sleeve being 1in. larger than the diameter of the cable. (2) The lead on the two

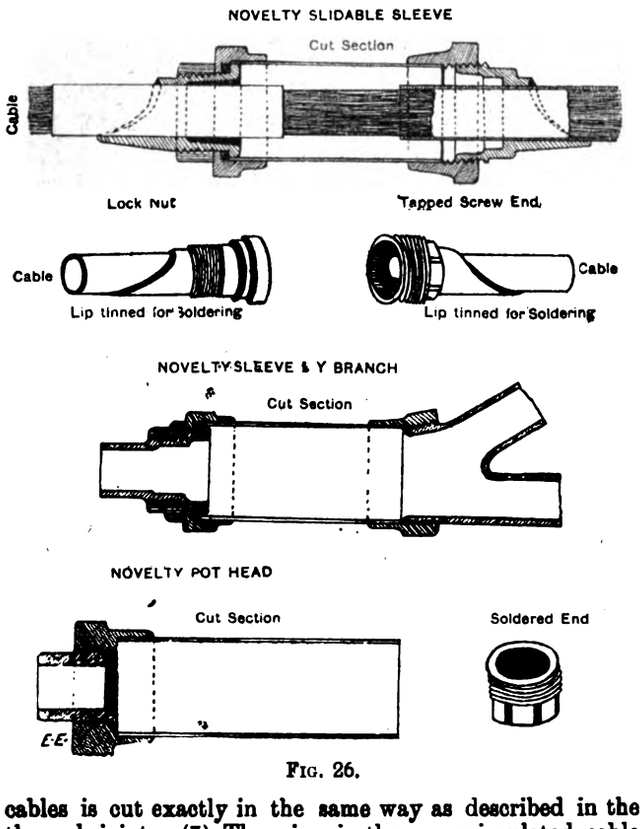

FIG. 26.

cables is cut exactly in the same way as described in the through joint. (3) The wires in the paper-insulated cable are opened out, wadding being packed down between the wires and the lead. (4) Boiling compound is then poured over the wadding and wires; this will prevent dampness from creeping into the cable while the joint is being made, and will also help to keep the hot compound from running into the cable. (5) The V.I.R. wires should have their tape or braiding taken off for a distance of 4in. and the rubber cleaned with naptha. (6) The joint is now made in exactly the same way as a straight-through joint. (7) The lead sleeve is then pulled carefully over the joint, so as not to disturb the paper sleeves, and is made permanent by a plumber's wipe at the bottom. (8) Heat the sleeve with a blow-lamp so that the compound when poured in will adhere to the inside of it. (9) Open out the V.I.R. wire so that the hot compound may fill up all the interstices. (10) Fill up the sleeve to within 1in. of top with boiling insulating compound. Great care must be exercised in pouring in this compound so as to hermetically seal the cable, and the compound must not be allowed to set hard. (11) The top of sleeve is now beaten in and then wiped. (12) It is advisable to put an air nozzle within 3in. of the pot joint. This air nozzle can be used for drying-out purposes or testing for air pressure on pot joint. For pot joints in the exchange Fig. 25 is a good pattern. These pots should be shaped and beaded at the top.

Several attempts have been made to overcome the necessity of wiping joints, and Fig. 26 illustrates a sleeve and pothead manufactured by the New Haven Novelty Machine Company in America, and so far as we can see there is no reason why it should not be used in England, as it has several advantages over the sleeves and potheads now used. In comparing the first cost between the Novelty system, which does not require skilled labour, and the lead-wiped joint, consideration should be taken of the fact that the Novelty slidable sleeve gives a flexibility which the wiped joint entirely lacks, in that inspection can be had at any time and as often as desired. To disconnect and reconnect again requires nothing but a wrench and a few moments' labour. The advantages of the slidable sleeve are still more apparent when the T branches are considered, not only on account of the saving of time and labour, but by the decrease in cost through not having to wipe the joints. The Novelty pothead also has the advantages of the slidable sleeve, and further, should occasion require, the Novelty, being made of brass, can be heated and the composition contained therein allowed to run off. The pothead further commends itself for the reason that it is not necessary to bend the pipe in order to wipe the joint, as at present, nor carry the molten metal up the poles. All that is required is a hot iron to cause the solder in the hub to flow. In cold weather the compound generally hardens, flowing into the pothead too thick, with the consequent result that it will not be properly or evenly distributed. By the Novelty system, the pothead being made of brass, a blow torch or lamp can be applied which will heat the compound to a boiling point, and thus ensure the desired result. This could not be done with the present lead pothead.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

637. With maximum traction trucks, what proportion of the weight should be put on the pony wheels to ensure reliability in operation? What is the best method of placing the brake shoes—both inside, outside, or alternating? What is a reasonable power consumption per car mile for closed cars 25ft. long, mounted on maximum traction trucks, and equipped with two motors of about 40 h.p. each?—C. H. S.

638. Explain and give best and safest methods of dealing with accidents which might happen as under. Supposing in a three-wire station, with voltage 440 and 220, you have a machine on the 440-volt bars, you have only one set of feeders connected +, 0, −. There is also a balancer capable of doing 50 amperes out of balance with maximum circuit breakers and starter on each outer and shunts cross-connected. If at some time you have 100 amperes each side on, and one of the outer main fuses happens to burn out, explain and give sketch as to what would happen, and the best and quickest way of righting things without the use of a battery and without damage to lamps. Also with circumstances as regards load same as above, and your machine minimum circuit breaker accidentally falls out, explain how to bring load on again with safety, your shunt resistance not being large enough to bring voltage lower than 300.—ELECTRO.

ANSWERS.

Question No. 629.—Describe what you consider to be the best lifeguard for electric tramcars at present on the market.

Best Answer to No. 629 (*awarded* 10*s.*).—The minds of authorities are considerably interested just now on the

Digitized by Google

subject of lifeguards, and to all tramway companies and to the public generally, one of the imperative needs of the times, in order to reduce the liability of accidents by electric cars, is the provision of a perfectly reliable lifeguard. There are a great number of lifeguards on the market just now, but the one which I consider to be the most reliable at the present time is the Philippson lifeguard, which has been known to save life on several occasions recently. This lifeguard is composed of a series of flat steel springs about 3in. wide by ¼in. thick, each one being

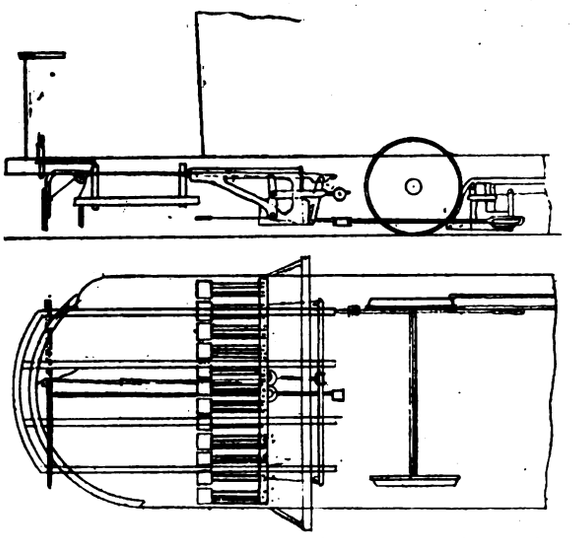

FIG. A.—Plan and Elevation of the Philipson Lifeguard and Brake.

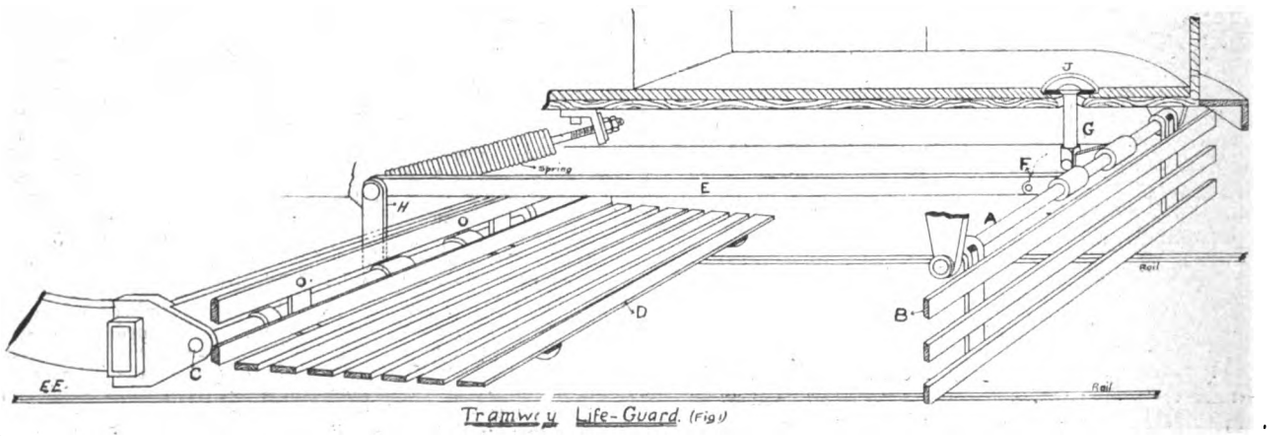
tipped with soft pliable indiarubber. These springs, which are made of the very finest steel, form 16 to 17 spades, and are divided so as to protect the full width of the car, and when brought into action each spade adapts itself as closely as possible to any inequality of the track immediately beneath the same, making it impossible for anything to get under. It is quite obvious that if the object in the way is to be picked up, there must be no possibility of any part getting underneath the guard, or it will become a "trap," and not a life saver. Not only so, but it is necessary that the object should be picked up with the least possible injury, and to do this something thin, soft, and pliable is required. This requirement is fully met by the rubber-tipped springs or spades. On the front of the lifeguard is suspended, the whole width of the car, a gate or trigger, which, when coming in contact with any obstruction on the trap, automatically drops the guard. This is so made that it forms two gates or triggers so as to act equally underneath the step, and also the full width of the car, and is also arranged that they are made to move backwards, and can be set very near the track without danger of being broken off when the car is going backward. It is necessary that this gate or trigger should not be fixed nearer than 2ft. in front of lifeguard, so that the two parts come into action without the possibility of any part of the obstruction getting under the guard.

It has been proved over and over again that children have been trapped and killed by falling sideways under the car between trigger and lifeguard. To prevent this, a side guard, free to allow any obstacle facing the car to go under and be picked up by the lifeguard is used, whilst anything falling sideways would be kept clear and cannot possibly get underneath the guard or wheels of car. Directly an object comes in contact with the hanging gate or trigger, not only does the lifeguard come into operation, but the car is immediately brought to a standstill by the automatic action of the emergency brake. This brake is a most powerful one, and although it stops the car very quickly, does so without any shock being experienced by passengers.

The sketch (Fig. A) clearly shows the form of the brake and its application. An important feature in connection with this brake is the fact that it can be operated by the motorman quite independently from the lifeguard, so that should any obstruction be seen a short distance ahead, the car can be stopped immediately, without waiting for the lifeguard to be brought into operation. Another point in connection with the automatic working of this brake is the fact that it can be set by the simple movement of a lever to act upon a car likely to run back down a steep incline. In this case it remains out of action whilst the car is ascending the hill, but directly a backward movement is made, the brake immediately comes into operation and stops the car. This brake is fitted to go under the wheels and get the weight of the car in a moment, and may be brought into contact in either case, between or outside the wheels. This lifeguard has engaged a large amount of attention at the exhibition held some time ago in London, and elsewhere, and has been put through a successful experiment before one of the Board of Trade inspectors. A very useful object lesson was furnished as to its utility some time ago. A young child, whilst crossing the track, fell right before an oncoming car fitted with this type of lifeguard, but without brake. The driver had not time to pull up, but as the child lay with its legs across the metals, the guard in question diverted him safely off the line, and thus probably saved his life, as he was able to get up and run away, suffering from nothing more serious than a fright.

This lifeguard can be fitted to any tramcar, and one of the principal tramway authorities of Lancashire are going going in for this type of guard, and have already fitted a number of their cars with same, and I believe are contemplating equipping the remainder also.—R. J.

Answer to No. 629 (*awarded* 7*s.* 6*d.*).—Since the development of electric tramcars, whose speed for average running exceeds that of the old horse trams, the requirement of a good, reliable, and, it may be said, harmless lifeguard for the protection of the public has been the cause of a great number of inventions and experiments. Although most lifeguard trials consist of placing a dummy on the track

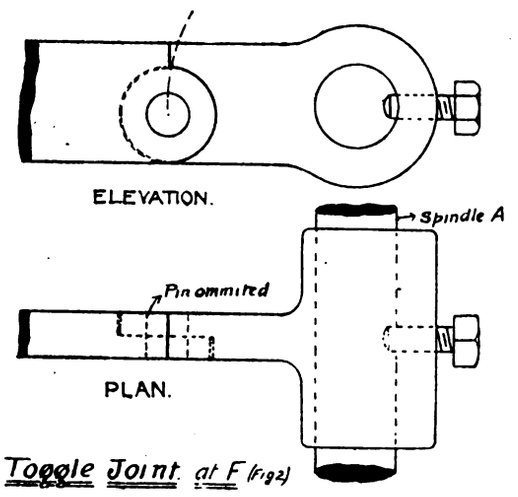


Tramway Life-Guard. (Fig 1)

and running the car up to it, thereby picking up the lifeless body, it does not follow that in the case of a human being (who, not like a dummy, has feelings), the unfortunate person will be picked up unhurt; anyhow, it is better to be picked up with a slight injury than to be mangled under a car. There are practically only two types of lifeguards—viz., the cow-catcher type, and the swing-gate and carrier type. Of these two, the latter type is mostly used in this country. The former type has a decided unsightly appearance, projecting out in front of a car. The accompanying diagrams show the construction of a very simple yet efficient lifeguard of the swing-gate and carrier

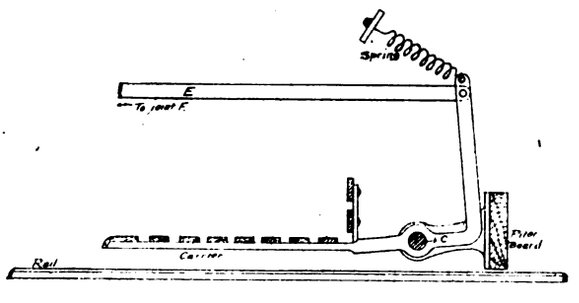
Digitized by Google

type, manufactured by Messrs. Hudson-Bowring Company, of Manchester, and most of the cars of that city being equipped with this type. The gate, B, which hangs from the bar, A, underneath the car fender, is so lightly balanced that at the least touch it falls inwards, thus turning the bar, A. Attached to this bar are two collared levers, F and G, so that, as the rod A turns the levers turn upwards. In doing so the first lever opens the toggle joint at F, and the rod E is pulled forward and actuates the bell-crank lever, H, on which the cradle or carrier is fixed. Thus the carrier is brought into an inclined position, the front edge resting on the track. The cradle is kept down on the rails by means of a strong spring, S,



Toggle Joint at F (Fig 2)

which serves a double purpose not only in keeping the cradle down, but gives a compressive action to the bar E, and thus preventing the toggle joint from opening unless the swing gate is pushed inwards, then after the gate has moved slightly inwards, thus opening the toggle joint, the spring is assisting the action, and brings the gate horizontally, and the cradle is lowered ready for picking up the obstructing matter. In order to reset the lifeguard, the driver of the car simply presses his foot down on the circular knob, J, which has been raised by the crank G; thus the toggle is kept shut owing to the additional tension placed on the spring by the backward movement of the lever H. Another feature of the spring is that of quickening the action of the lifeguard, also should the obstruction not be very high, and thereby only catching the bottom part of the swing gate, the mechanism will not fail to cause the cradle to drop



Side View of Carrier and Lever (Fig 3)

down. This type of lifeguard is found from experience to be very reliable in its action, which is mainly due to its simplicity of construction; it is also not a very expensive type, which is another consideration on behalf of the tramway companies. Of course, there is no lifeguard yet invented which eliminates the danger of injury to a person through being knocked down by the car. Their chief object is to prevent further injury from getting entangled with the car mechanism. In the author's opinion the "cow-catcher" type of lifeguard is positively dangerous, as it is generally several inches above the level of the rails, and the event of a broken ankle or crushed arm is highly probable, even though this guard, due to its shape, may be of some use in pushing aside the obstruction.—H. R. G.

Answer to No. 629 (*awarded* 5*s.*).—There are principally two systems of lifeguards—one for picking up the person, the other rolling the same out of the way. The first system is again divided into those worked by the motorman and those working automatically by means of a front shield suspended below the dash-board, which, when touched, causes the guard or fender fixed in front of the wheels under the platform to drop on to the permanent way, and thus intended to pick up the person. Further, in regard to the picking-up system, there are again those that are fixed and projecting in front of the dash-board, and which are generally worked by the motorman, chiefly used in America, but also on some lines here. The automatic picking-up system, mostly in use in this country—viz., London United Tramways Company, Blackpool and Wolverhampton Corporations, etc.—seems to be preferable to the system worked by the motorman, as accidents chiefly arise not in view of the motorman, but by passenger and vehicular traffic suddenly coming from side streets or crossways, consequently the motorman has not the time to give preference in working his brakes or lifeguard release stop. Further, at night the difficulties of observing anything coming in dangerous proximity to the car are augmented. This automatic guard system is well represented in the Wilson and Bennett, the Tidswell, the Royles patent guards, and others. Of these, the Tidswell is the cheapest, the fender being constructed of wooden laths, while the others are made of iron or steel netting. The type of guard worked by the motorman, fixed in front of the car dash-board, is represented by the patents of the Providence car fender of the Consolidated Car Fender Company, the G. Hepwood patent fender, the Parmenter fender, and others, which seem to give greater opportunity to collisions with vehicular traffic than the fenders fixed below the car. In reference to the efficiency of both these systems of fenders, much depends on the method of attachment to the car. If the same be fixed to car body they necessarily are exposed to the oscillations of the car body, and, therefore, are less reliable in picking up than those fixed to the car truck frame. Nevertheless, it was found, through some unfortunate accidents occurring at Liverpool, this picking-up system was unreliable, and the authorities ordered a change to be made to the rolling-out system—*i.e.*, pushing the person away from dangerous proximity to the car. In this latter method a pair of wedge or V-shape form boards are fixed stationary to frame of truck under car body, fitting as close as permissible to the permanent way. Such a system is now in use at Liverpool—known as the Bellamy patent guard—and resembles greatly a similar apparatus of a wedge-shaped elastic cushion patented in 1884 and tried then for horse cars. The great point in lifeguard construction or design is to reduce the blow struck to a minimum, in either the pushing away or picking-up methods, which necessitates some part of the guard to be constructed of an elastic nature material. From the writer's experience, consisting of a very varied tramway construction experience in different parts of the country, both the above systems seem to have their good and bad points, leaving very little to discriminate as to which is the better or more efficient. However, summing up the conclusions to be drawn from the merits of the two systems, the rolling-out method offers a better range as regards reducing the blow struck, less mechanism to get out of order, therefore less maintenance in comparison with the other system; yet, perhaps, it may not be so reliable due to its not sliding on the line, and so allow a small limb, arm, or leg to get underneath and be pinned down. But cases have occurred where the pick-up system has not only failed to pick up, but actually rolled over the object on the line, thus allowing the same to get underneath the wheels. Considering, finally, all these different points, the solution of this problem seems not to have reached finality and absolute perfection, thus being still liable to great improvement.—E. S. CONRAD.

Question No. 630.—Describe the action of the sight-feed lubricator for cylinder lubrication. Give sketch.

Answer to No. 630 (*awarded* 7*s.* 6*d.*).—A section of a sight-feed lubricator is shown in Fig. 1. B is a brass cylinder with a hollow piston rod, A, and piston, C, with oil on one side and steam on the other side; S is the sight feed, regulated by valve E; and Z the connection to the steam supply, regulated by the valve Q. In cases where

Digitized by Google

the lubricator is fitted near to the cylinder a condensing coil, M, is placed in circuit between the steam-pipe and lubricator, as shown in Fig. 2,, where N is the steam-pipe

The action of the lubricator is as follows: Having filled the cylinder, B, with oil and the sight-feed, S, with water, the valves, E and Q, are opened and also the steam-cock, R.

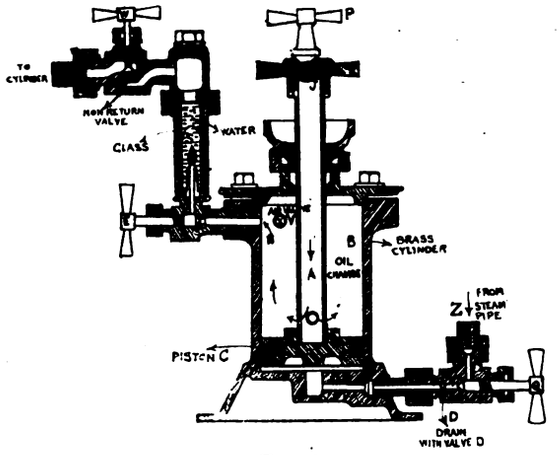


FIG. 1.

The steam being condensed in the coiled pipe, M, forms water, and forces the piston upwards. This forces the oil through the glass sight-feed chamber drop by drop, and which rises through the water in S, than which it is specifically lighter, and thence to the cylinder. The method of filling the lubricator is to remove plug, P, and open air-valve, V, and pour oil in at J until it shows at V; then screw down the plugs, and open inlet valve at Q half

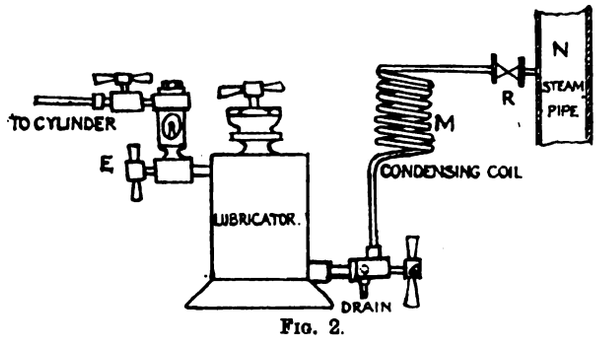

FIG. 2.

a turn. Open valve W, and then slowly open E and regulate to feed required. To refill, close valves E and Q, then open D to relieve the pressure and V to allow the piston to descend, and fill as before. In cases of low pressures (50lb. and under) the piston rod is extra large to give it increased area, and on compound engines a separate feed is usually supplied to each cylinder.—L. B. H.

Answer to No. 630 (*awarded* 7*s.* 6*d.*).—Sight-feed lubricators are of two kinds, known as single-connection type,

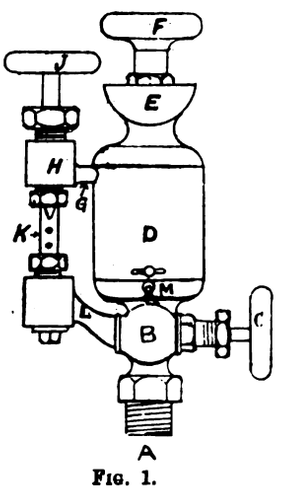

FIG. 1.

shown in Fig. 1, and double-connection type, shown in Fig. 2. In the single-connection type the receiver, D, is filled by unscrewing the plug, F, and pouring oil through the cup, E, and then reinserting the plug. On opening the valve B by handwheel, C, steam is admitted at A, and is conducted by a small pipe through the centre of the receiver to the top of the chamber; here it comes in contact with the cold oil, and is condensed and falls to the bottom, causing the oil to rise by displacement and overflow by the pipe G and valve H, through the sight tube, K, along the pipe L to opening at A, where it flows into the steam-pipe leading to the cylinder, the rate of feed being regulated by the valve H. When the supply of oil has been exhausted, the receiver, D, has become filled with water of condensation; this is drained off by the small drain tap, M, and the lubricator is ready for filling again. In this type the oil drops downward through the glass tube, which is filled with steam when working.

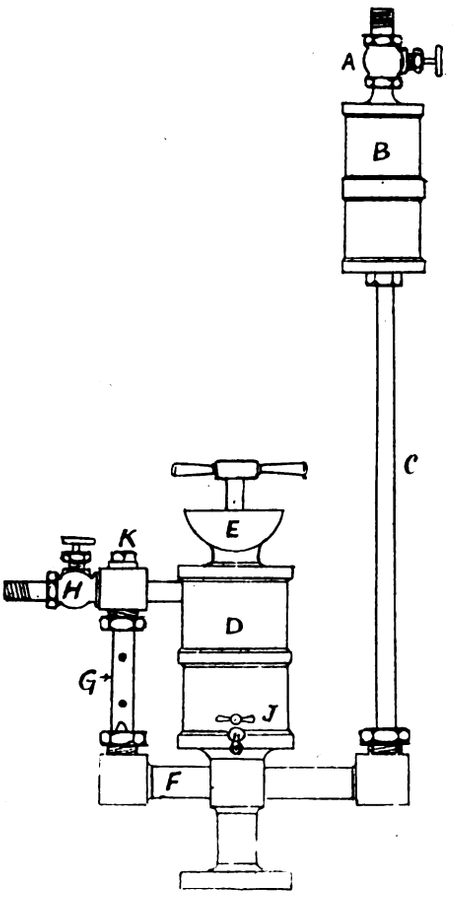

FIG. 2.

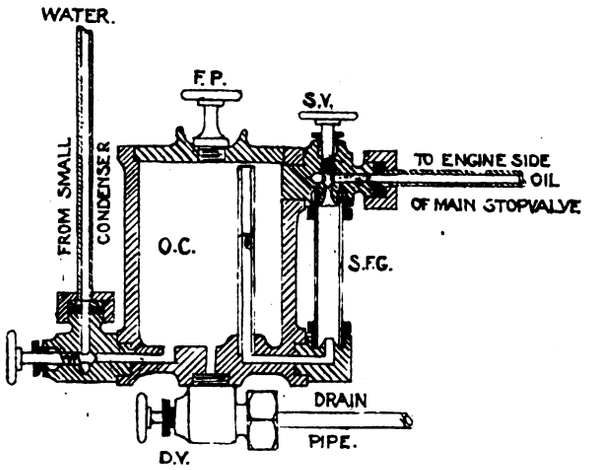
In the double-connection type the oil receiver is filled in the same manner as in the previous one. The sight tube is then filled with water by removing the plug, K. The valve A is connected to the boiler side of the engine stop-valve, the valve H being connected to the engine side of the same. Steam is then admitted at A, and on entering the condenser, B, is condensed, and fills this and the vertical pipe, C, with water. On opening the valve H, the pressure on both sides of the oil-chamber is equal, but the hydrostatic head formed by the water in B and C causes the water to rise to the top of the chamber, D, and forces out the oil along the pipe F, through the sight tube, G, and valve H, to the steam inlet to cylinder, the rate of feed being regulated by the valve H. When the supply of oil is exhausted, the water in the receiver is drained off by the small drain-tap, J. In this type of lubricator the glass tube is filled with water, and the drops of oil float upward through this when working. It is capable of more regular adjustment than the single-connection type. The condenser, B, is made in various shapes, and in some cases consists of a spiral coil of copper pipe, the object in all cases being to obtain a comparatively large cooling surface to procure efficient condensation.—STOW.

Answer to No. 630 (*awarded* 5*s.*).—By reference to the sketch herewith of a sight-feed lubricator, or "impermeator," as it is sometimes called, the various parts can be clearly seen and its action followed. In lubricators of this type

Digitized by Google

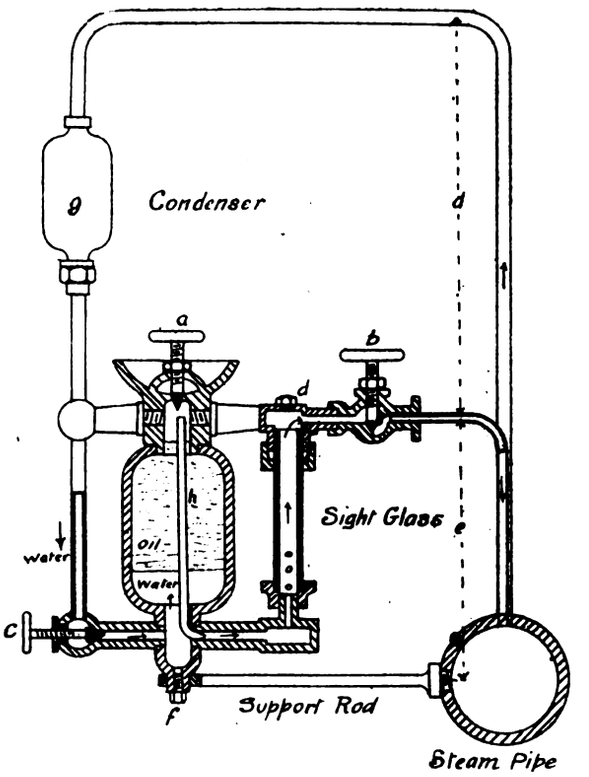
advantage is taken of the fact that oil floats on water when the two are mixed, it being the lighter of the two liquids. In the sketch it will be observed that the apparatus consists of a cylindrical case with a glass tube at one side of it, and various valves for controlling the oil and water. There is a pipe connection from the steam-pipe, the steam in which is to be lubricated, to a small condenser (usually situated a foot or two, sometimes more, above the lubricator) which is generally in either of two forms—namely, a small coil of the connecting pipe, or a small brass chamber which forms part of the pipe, and is really only an enlargement thereof The steam from the main steam-pipe is condensed in the condenser owing to loss of heat due to radiation from the external surface of the afore-mentioned coil or chamber. The water resulting from this condensation flows down the pipe to the regulating valve, R V. On the other side of the lubricator there is a pipe leading in most cases to the engine side of the stop-valve on the engine to which the lubricator is attached, this pipe being provided with a stop-valve close to the engine. The valves, R V, D V, and the one on the pipe leading to the stop-valve being shut, the following is a description of the method of charging and working the lubricator. The sight-feed glass, S F G, is first filled (through the aperture at top of it when the S V valve spindle is removed) with either water, glycerine, or a concentrated solution of salt in water. The spindle is then replaced and this valve shut. The oil chamber, O C, is next filled with cylinder oil (when the filling plug, F P, is removed). When chamber is full the plug is replaced, and the lubricator is now ready for action. The valves, S V,



and the one at engine stop-valve are now opened full, and R V is opened very gently, allowing the water in pipe from the condenser to enter the bottom of the oil chamber. The oil floats on this water until it overflows into tube, T, and thence to the bottom of S F G, where it can be seen ascending on the way through S V to the pipe leading to the engine. The amount of oil required (usually a predetermined number of drops per minute) is regulated by R V until the proper rate of feed is obtained. If the pressures in the two connecting pipes are equal, the pressure on the oil due to the head of water in the condenser forces the oil into the engine, and by connecting condenser pipe to main steam-pipe and the other pipe to engine side of valve on engine, there is a difference of pressure in the two pipes, which further assists the action. In some lubricators of this type the condensation of steam takes place in the oil chamber itself, but the action is just the same as already described. When the oil has all been fed to the engine, the water which has displaced it is run out through the drain valve, D V, making room for a further charge of oil.

There is another type of sight-feed cylinder lubricator, which is a kind of force pump, the plunger being pressed down on the oil in the chamber by means of a ratchet and screw mechanism worked from some reciprocating part of the engine, and the oil forced through a sight-feed glass into the steam-pipe. This type is not so much in use in central stations, but is common on marine engines.—J. WALKER.

Answer to No. 630 (*awarded* 5*s.*).—The importance of an effective system of cylinder lubrication is realised by all steam users. The cylinders of steam-engines of small and medium size are usually lubricated by the introduction of oil into the steam-pipe or steam-chest. Thus the steam becomes saturated with oil and carries it to all points which are to be lubricated. An important feature in cylinder lubrication which is sometimes neglected, is that of a uniform supply of oil and at the proper rate; for this object the sight-feed lubricator is undoubtedly an essential type Insufficient oil to the cylinder increases frictional wear between the walls of the cylinder and piston; on the other hand, if too much oil is admitted it becomes the source of a positive nuisance in clogging up the valve chest and steam passages, and if the exhaust steam is condensed and pumped back to the boiler in an impure condition, the oil which is mixed therein would deposit on the inner surface of the boiler plates, thus being another source of trouble. However, to carry out the old saying, "Prevention is better than cure," it is always advisable to use an oil separator to rid the condensed water of oil. The accompanying sketch shows one of the numerous types of sight-feed lubricators, although they are nearly all of the "displacement principle." The oil chamber is charged from the screw plug, *a*, and the sight glass is filled with glycerine or strong salt and water solution; *g* is the



condensing chamber, which is in communication with the steam-pipe, water being formed from the steam runs down the pipe to the valve *c*, and when this valve is open it finds its way into the oil chamber, consequently lifts the oil until it overflows down the tube, *h* It then passes up through the liquid in the glass sight tube, and passing the valve *b*, away to the steam-pipe, where it is intermingled and carried over to the steam-engine cylinder by the steam supply. In this arrangement the pipe leading to the condenser must be taken from a point in the steam-pipe at least 6in. further away from the engine than the discharge pipe of the lubricator. In order to start the lubricator the valve *b* should first be opened, and then gradually open the valve *c*. The drops of oil will be seen to rise in the sight glass, and by adjusting the valve *c* the quantity of lubrication can be varied to any desired extent. Both valves, *b* and *c*, should be closed when the engine is stopped.

TRADE.

There has been a plethora of presidential addresses during the past few days, each of which is well worthy of careful consideration, but to present them fully to our readers is a matter of impossibility. We shall, however, try to deal with some of the points raised as opportunity presents. Mr. E. W. Cowan's address to the Manchester Section deals somewhat exhaustively with the all-absorbing topic of the day—home and foreign trade. Every paragraph is worthy of discussion, in that he deals seriatim with particular phases of the question, each of which has its own bearing upon the subject. The text relating to the home trade is fairly given as follows: "If we look down the published share lists of our electrical manufacturing companies, we can, I think, only come to one conclusion, and that is that our industry is sick." The address then goes on to give reasons why this is so. By implication we are told the investing public does not rush into these concerns; thus we infer many works are carried on with too small a capital. Investors do not forget the twelve million pounds lost in the early days of the boom in electric lighting, and we have the dogmatism "that ordinary share capital in manufacturing companies should bear an interest of not less than 10 per cent. to justify its being rated at par value." Influences such as the late war, over-production, and consequent dumping from competing countries, and the mistaken notion that money circulation, and not utilisation productivity, may be good, and their bearing on the industry is discussed. One point of the utmost importance at the present moment is mentioned. This country used to find its own capital and invest largely abroad. Of late years other nations have largely invested their capital in this country—a fact undisputed and undisputable, much to our detriment, for if it was a sign of prosperity here to largely invest abroad in order to get interest on those investments and increase our prosperity, it must follow that it is to our disadvantage and the benefit of someone else if foreign investments are made here. It is said that "fools rush in where angels fear to tread." Nothing could be clearer than this when one considers the average speech on the fiscal question. How often do we read that England cannot be in a bad way because she imports large amounts of gold. If foreigners are investing here, it is easy to account for these imports. Assume a newly-discovered island in the Pacific. Assume that some wanderer finds fertile tracts—finds mineral wealth. Does it follow that the island must share the total prosperity because it imports gold? Surely the prosperity is a divided quantity, the investor getting his share. The island may be exploited for the benefit of non-residents. Hence in England we may—it does not follow that we do—import gold to our own detriment. But to go back to Mr. Cowan. He points out that the manufacturer ought to be insured against the chances and risks of the business, and then once more calls attention to certain badly-worded clauses often met with in specifications, also to the losses incurred by the lock-up of capital through delayed payments. These are questions which have been discussed *ad nauseam*. The parent Institution has taken cognisance of the subject and issued model clauses, which if generally accepted will assist in overcoming these difficulties. Two other points of the greatest importance may be mentioned—the imposing of conditions upon British manufacturers both as to design and construction which are not and cannot be imposed upon foreign manufacturers. A standard type is more often than not accepted from the foreigner, but not at home. Perhaps the foreign type is really better than

Digitized by Google

that at home, but all our investigations go to show that perfection or non-perfection has little or nothing to do with the matter. Mr. Cowan thus sums up the consulting engineer: "A consulting engineer does, in my opinion, too much and too little. There are, of course, notable exceptions, but I am speaking generally. He will declaim against English manufacturers neglecting to standardise, and in his own work make standardisation impossible. I have referred to the fact that in general the consulting engineer takes no responsibility—every manufacturer has had experience of this. I will give one instance, which is a typical one. A consulting engineer having overlooked in his drawings to make provision for head-room for a travelling crane, one of his contractors was put to considerable expense in remaking some apparatus to suit the actual conditions, consenting, as usual, to make no charge for doing so. In carrying out the alteration the contractor's man broke a window, whereupon the consulting engineer wrote to the contractor to the effect that he was rendering an account for the repair of the window. That consulting engineer was lacking in a sense of humour, but his attitude is typical of that of the general body of consulting engineers. It must have been a consulting engineer who invented the clause to the effect that the contractor was bound to satisfy himself that there were no mistakes in the drawings issued for him to work to." The other point is thus put, "Why is it that resident engineers are often selected only upon the grounds of their technical experience? Many resident engineers have been installed who have had no experience or training in business." That is so, and is a misfortune; but, on the whole, the resident engineers have shown an immense capacity for business. A resident engineer to a company is in a different position to one for a municipality. It is the latter that have evoluted great business capacity. Indeed, all we know of organisation, of business methods, of improvements or mistakes, come from them. Here, then, are some of the views concreted in this address The longer portion deals with the fiscal question, but that we leave for the present. Mr. Cowan has put the manufacturers' view; the other, that of the engineers, will undoubtedly be put forward ere long as a reply. There cannot be too much discussion upon the various points.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

SUPERHEATED STEAM.

SIR,—Mr. George Wilkinson's experience with reciprocating steam-engines, as I gather from his letter published in your last issue, appears to have been unhappy. While one can be sorry for him, his conclusions are really too hasty to be passed without remark. There is at least one electricity works where steam superheated very considerably more than 50deg. F. has been in regular use for the past five years in quick-revolution reciprocating engines. The engineers running the plant are quite happy about it, and would be glad to get the steam at a higher temperature if the superheaters would only give it. There has not been an accident in the five years due to the use of superheated steam other than the failure of a copper bend inadvertently left in the main steam-pipe when the use of saturated steam was discarded. Valve faces, cylinder liners, piston rods, etc., that have been subjected to superheated steam for five years are still in excellent condition, and the cost of engine repairs will compare favourably with that of most undertakings using the same type of plant. During the whole of this period the cylinder oil used has not cost more than 1s. 10d. per gallon delivered at the works, and the quantity used is strictly moderate.

There seems generally to be considerably more fear of superheated steam among engineers in charge of steam-engines than there is any occasion for.—Yours, etc.,

E. LL. I.

THE "PHIELASHOK."

SIR,—Our attention has been drawn to a letter in your issue of the 6th inst. from Mr. J. Isaacs with reference to our instrument called a "Phielashok," and it is evident that that gentleman has not understood the method of applying the instrument. Your other readers will have no doubt grasped the fact from your article that the "Phielashok" consists of such a high resistance placed in series with the body as to reduce a violent shock to a slight one, or to a tingling only. We are surprised that anyone should place a hand *directly upon* any terminal that *may be* "alive," as Mr. Isaacs would apparently do, when he should touch it with a "Phielashok," in which case, should there be an earth, it would be indicated at once.

If the operator follows our directions, or even uses ordinary common-sense when applying the instrument, there is no fear whatever of receiving a violent shock, even on earthed systems, which your correspondent regards as dangerous; and it was for such systems especially that the "Phielashok" was designed. We do not claim that it is any *better* for testing, whether certain wires, etc., are "alive" or not, than the old-fashioned method of using an incandescent lamp; but it stands to reason that it is far more convenient and more easily and rapidly applied.

We do not know whether Mr. Isaacs has used a "Phielashok." We should think not; but if he will let us know whether he is particularly susceptible to shock or not, and the approximate voltages of the circuits with which he has to deal, we shall be happy to send him one of the instruments to try.

In conclusion, we would mention that we have received numerous orders for the "Phielashok," more especially from corporation electrical engineers for their own and their staffs' use.—Yours, etc., OLIVER AND CO.

STEAM TURBO GENERATING PLANTS.

SIR,—Permit us to assure Mr. Wilkinson that we have not intended to insinuate anything beyond what we have said in our letter. We called the statements extracted from his paper misleading because these incorrect statement were largely used in his argument. As he does not in his reply dispute the inaccuracies, the remarks in our previous letter still apply to the facts. Mr. Wilkinson is evidently not aware of the extent to which superheated steam is being used with reciprocating engines in central stations. Hundreds of our engines working under superheat, some for four or five years, show that the troubles Mr. Wilkinson anticipates are purely imaginary. Our triple-expansion engines, expressly built to use superheat without risk, have shown benefits so great that nearly all up-to-date central-station engineers have insisted on superheat for some time past in their specifications.

The difficulty with the turbine under superheat is due to the expansion, which necessitates a considerable increase of the usual clearance to avoid the risk of stripping the blades when the maximum possible superheat comes on. This might be arranged for if the superheat could be kept constant, but as this is impossible, there must, on account of the excessive clearance, be a large increase of leakage under the normal working conditions.

As Mr. Wilkinson prefers to compare results "under actual daily working conditions" and to have "the outcome of every-day practice," we submit the accompaning Table A, giving the results of a year's working of all the provincial central stations we know of where steam-turbines are used to any extent for electric lighting. The figures are taken from the latest official returns, and the costs are given in pence per unit sold published in the electrical papers, and for comparison we give from the same official returns an equal number of stations with reciprocating engines under approximately similar circumstances as to costs of labour, fuel, output, etc. The results are interesting, and show that the steam-turbine stations on the average are quite 50 per cent. worse than the reciprocating engine stations,

not only in the fuel used, but in the total cost per unit of electricity produced.

These official returns if brought up to date might possibly modify the results in favour of the reciprocating engine or otherwise by a decimal point or so, but the superiority shown by the reciprocating engine is too large to enable steam turbine advocates to quibble it away at present. We may say that the reciprocating engine stations have been chosen by us with as much absence of bias as possible, and we might have selected for example 38 stations showing an average of ·41 for fuel cost, instead of the ·51 we have accepted for comparison sake. These figures are the only official ones at present published, and they should, in our opinion, at least give pause to the enthusiasts who want to rush the steam-turbine for central-station work.

Turbine enthusiasts appear to lose sight of the fact that the steam-engine has not been standing still during the last few years, but has been largely improved by the judicious use of superheated steam in specially designed engines. The reciprocating steam engine, in fact, is still far ahead of either gas-engines or turbines for economy of fuel on the average station loads; and for comfort and reliability of running, on which the reputation of the station more immediately depends, there is no question as to the superiority of the steam-engine.—Yours, etc.,

BELLISS AND MORCOM, LIMITED.

MANCHESTER LOCAL SECTION, I.E.E.

The inaugural meeting of the present session of the above section took place on Tuesday night, and was quite a record gathering, over 250 members being present. A happy thought had given a double-barrelled character to the proceedings, which consisted of Mr. E. Cowan's address as chairman, and a demonstration of the properties of radium by Dr. Schuster. Mr. Cowan's text was "The Manufacturer's Worries," and he dealt, firstly, with the necessary evil of consulting engineers' peculiarities; and, secondly, with the unnecessary evil (according to Mr. Cowan) of Protection. On the general subject of progress he remarked that a glance down the published share lists of electrical manufacturing companies showed that the industry was sick. Taking the ordinary share capital of the companies manufacturing only electric light and power apparatus, which in the dozen or so companies listed in the electrical Press amounted to something more than 3½ millions, they found that nearly half the capital was bearing no interest at all. He maintained that the manufacturing industry had been hindered and hampered at home in its development, to the material detriment of the industry as a whole. The first part of the address was enlivened by anecdotes of consultants and their generally recognised one-sidedness in dealings between producer and purchaser, and it was fortunate for the peace of mind of the chosen of the profession present that there was no discussion. Note was made of the awkward position of a contractor when having to deal with both a consultant and a resident engineer when the two did not agree; and the very safe tip of backing the seemingly less important resident was given. With regard to the opinion which was held in some circles as to the unprofitable nature of municipal contracts, Mr. Cowan instanced the system of deferred payments, that is so rife in specifications, as a means of unprofitably locking up money to the detriment of trade. The likelihood of manufacturers combining to withstand unjust clauses in contracts was shown to be small, on account of the potentiality of foreign competition and the lack of business. Another point which Mr. Cowan said is injurious to the home manufacturer is that he is hindered in standardisation owing to the demand for alterations in designs, according to the opinion of the engineer. He proceeded to pass some criticism upon resident engineers, complaining that many are installed merely on account of their technical experience, and have no experience or training in business. A grave injustice is thus often done to contractors. The second part of the address was a review of the fiscal question, in which a hydraulic simile did service, and a great number of general conclusions were arrived at. Mr. Cowan finally summed up for Free Trade, on the general grounds that English manufacturers wanted "bucking up," and that Protection would cause them to go to sleep, with bad results to the industry.

A hearty vote of thanks was proposed by Dr. Bowman, seconded by Mr. C. D Taite, and carried with acclamation; and in reply to this Mr. Cowan absolved all the consulting and resident engineers present from connection with his remarks upon their class, as being the necessary exceptions to the rule.

Dr. Schuster's demonstration, though interesting to the physicists present, fell rather flat with the general body of engineers and commercial men, and the experiments were hardly clear or conclusive enough to do more than amuse. The placing of a piece of radium between opposite poles to induce a discharge therefrom, for instance, would have been equally successful with any piece of metal used as an arc striker; and the much-marvelled-upon luminosity of the substance in the dark reminded one of common or garden phosphorus. Dr. Schuster answered questions on the subject afterwards, when the unknown properties of the metal were very much in evidence. A vote of thanks to the professor concluded the proceedings.

NEWCASTLE LOCAL SECTION, I.E.E.

The following is an abstract of Mr. Gerald Stoney's address to the Newcastle Branch of the Institution of Electrical Engineers, delivered on Monday, Nov. 16, 1903:

This branch of the Institution of Electrical Engineers has now been is existence for four years, and the membership has risen steadily from 93 at the time of its inauguration to 152 at the present time.

A subject in which great interest is being taken is the education of engineers, and this has produced most diverse opinions. All, however, are practically unanimous that it is necessary to combine practice with theory, but as to the best way of doing this there is much difference of opinion.

Digitized by Google

The best way, however, seems to be the "sandwich" system, in which the theoretical and practical training are carried on concurrently. Stress should be laid on the importance of letting a boy early in life learn the use of tools, and this can, as a rule, be best accomplished by letting him have an amateur workshop, in which the average boy will, with a little encouragement, spend a part of his spare time.

Modern languages also are of great use to an engineer, and he should be taught both to read and speak them. Latin and Greek may well be left out, and it is maintained that the German grammar is as good an education for the mind as the Latin grammar, besides being of practical use to an engineer. Mathematics should also be taught from a practical point of view, so as to enable the student to make use of them in the actual problems which occur in practice.

In thus, however, urging a practical education for an engineer, no one more than an engineer is aware how much is owing to those who pursue science for itself apart from mere monetary gain. Without the investigations of the immortal Faraday, out of which he deliberately refused to make any monetary gain, where would the whole of our modern electrical engineering be? Without the investigations of Faraday, Maxwell, Herz, Fitzgerald, Lodge, and many others, Marconi could not have made wireless telegraphy the brilliant success it has been. In almost all cases the way has been paved for the engineer and the commercial man by seekers after knowledge, which they have given to the world freely and without stint, and it is hard to say what bearing investigations in pure science may have in the future. Such discoveries as the fixation of atmospheric nitrogen, and thus the formation of nitrogenous manures, may be of great importance to agriculture, and the formation by electrolysis of many of the organic compounds found in plants may eventually give us a clue to the mystery of life, which, along with gravitation, is one of the great mysteries of Nature still to be solved by man.

The distribution of electricity for power, lighting, and traction has made enormous advances, and there is no sign of this rate of progress slackening. In this district we have the first of the great power stations at Neptune Bank, Wallsend-on-Tyne, and soon a second one at Carville will be at work. During the past 15 years the size of engines and dynamos used had steadily risen from about 100 kw. to from 4,000 kw. to 5,000 kw. at the present date. In this connection the Parsons steam-turbine has taken a notable part. This was invented by the Hon. C. A Parsons, F.R.S, in 1884, and the first engine was of about 10 h.p., while now turbines up to 8,000 h.p and 10,000 h.p are being made. The low first cost, small steam consumption, absence of reciprocating parts, and small foundations, as well as reduced attendance and upkeep, have made this type of engine largely adopted for driving dynamos and alternators, as well as for the propulsion of ships and other purposes.

A great field is opened up by the discovery of cathode and other rays, in which we seem to be dealing with individual electrons instead of with masses of them. Recently there is the marvellous discovery of radium, which not only gives forth three distinct sorts of rays, but also is warmer than objects surrounding it, and is, therefore, constantly pouring energy, the exact source of which is still in dispute. These researches in molecular physics may some day enable us to deal with individual molecules instead of with masses of them, and thus it may be possible to tap the great source of energy existing in the atmosphere by the help of the "Sorting Demon" pictured by Clark Maxwell, and thus utilise for the service of man the energy of the atmosphere without the consumption of coal or other fuel. And looking back on the advance made in the last 100 years, who will say it is impossible? Fancy our grandparents in the "Flying Scotchman" at 60 miles an hour. What they would think of telephone, telegraph, or gramaphone? What would the effect be on a stage coach if it met a bicycle or motorcar? Some of these things would have been declared impossible even within the memory of many of those here present.

TRADE NOTICES AND NOVELTIES.

Lundberg's Accessories.

The recently-issued catalogue of Mr. A. P. Lundberg, of 477 to 487, Liverpool-road, N., contains some new electric light accessories which will be welcomed by electrical engineers. Of the well-known standard switches and other accessories made by the firm we cannot again give a description, but the following improvements in detail are worthy of illustration. The first of these (Fig. 1) shows a new and patented method of

FIG. 1.

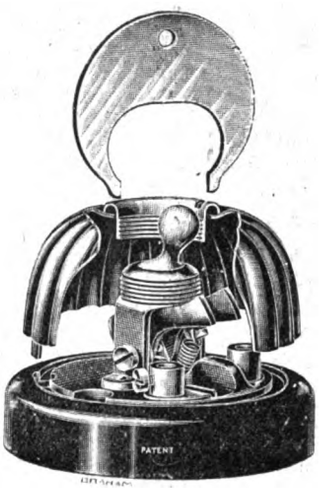

FIG. 2.

securing china switch covers on to either the "Pivot" or "Century" switch. For this purpose a screwed collar which keys with three projections into the china cover is used. The result is more mechanical than the usual method, and it relieves the roof of the cover from strains which frequently have caused fractures. The china cover secured in this way is much more satisfactory than one in which the material of the cover has a thread formed in it. A variation of this method of securing any switch cover is shown in Fig. 2, which gives the locking so often required. In this case the nipple is not keyed into the cover, but holds the same in position by means of its upper flange. The nipple is screwed into place by means of a key, shown in the illustrations, and without which the cover cannot be removed. This feature is of great service in switches which have to be placed in office corridors, asylums, schools, hospitals, etc. Fig. 3 illustrates one type of the Pivot

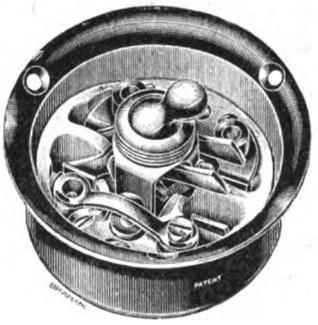

FIG. 3.

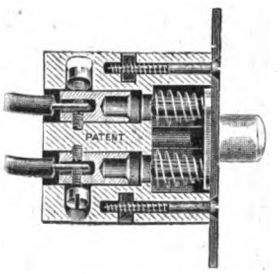

FIG. 4.

switch arranged for two-way working. As will be seen, it is contained in a brass box for sinking into the wall. Fig. 4 is a section of Mr. Lundberg's improved door contact for lavatory lighting. The general design of this is not new, but it has been slightly altered so that it may be constructed in porcelain instead of in fibre, which is a great improvement. As will be seen, the terminals are exceptionally well shielded, and the contact made when the plunger is forced in is good. The illustration is full size, and the contact can be sunk into any door frame.

PHYSICAL SOCIETY.

At the meeting of the above society on Nov. 13, Dr. R. T. Glazebrook, F.R.S., president, in the chair,

Sir Oliver J. Lodge read a paper on **"Means for Electrifying the Atmosphere on a Large Scale."** Twenty years ago the author was engaged with Mr. J. W. Clark on an investigation of the dark spaces seen near hot bodies placed in illuminated smoke. The existence of these dust-free spaces was discovered by Tyndall, and the phenomenon had been investigated by Lord Rayleigh. Tyndal worked with high temperatures, and attributed the effect to the burning of the dust near the hot body. Such, however, cannot be the case, as the spaces exist

Digitized by Google

when inorganic dust, such as oxide of magnesium, is used. The conclusion at which Messrs. Lodge and Clark arrived (see *Phil. Mag*, 1884) was that the result was due to an aerial bombardment from the hot wire which drove the particles away, and they tried the effect of electrifying the hot body to see if there was any modification of the dark space. A new phenomenon was discovered, the whole of the dust being driven to the sides of the containing vessel. This experiment was shown by the author at the British Association meeting in Montreal in 1884, and subsequently, on a larger scale, at the Royal Institution. In the latter experiment two pieces of wire gauze, connected to the terminals of an electric machine, were placed opposite each other in a smoke-filled chamber, through which a current of smoke was slowly passing. Upon electrifying the plates the smoke ceased passing, the dust particles cohered, hovered in the air, and were either driven to the sides of the chamber or fell to the bottom. In the case of mist electrification of steam in a bell jar converted it into fine rain. It seems, therefore, possible that rain might be produced by the electrification of a cloud. Sir Oliver Lodge has tried at Liverpool to disperse fogs by discharging electricity into them. For this purpose a large mast was erected on the roof of the University College buildings. It terminated in a bundle of points, to which electricity was conveyed from a Wimshurst machine by a wire supported by specially-constructed insulators. In order to drive electricity from a point far removed from a surface a high potential is necessary, and sometimes a large gas flame was used to supplement the points. Upon one occasion the discharge of electricity from the flame was sufficient to keep a clear space of 50 or 60 yards radius in a dense fog. The author had hoped to induce the Mersey Dock Board to try the principle on a large scale, having a series of positive discharges on one side of the river and a series of negative discharges on the other; but he felt a certain reluctance in recommending the method to practical men so long as it was necessary to derive the current from a Wimshurst machine. A dynamo would be a more suitable generator if it were possible to get a sufficiently high potential. The way out of the difficulty is to rectify a high-tension alternating current, and Sir Oliver Lodge has for some time been considering the possibility of doing this by utilising Cooper-Hewitt mercury lamps. A study of these lamps has led him to believe that their rectifying power is much assisted by the outside metallic coating which surrounds the mercury electrode, and which is connected to the positive terminal of the lamp. In order to rectify an alternating discharge, four lamps are so arranged in the form of a quadrilateral that, when the leads from the terminals of an alternating transformer are connected to two opposite corners, two unidirectional currents are obtained from the other corners. Experiments have been made at Birmingham by sending the current from a high-frequency alternator (3,000 ⌢⌣ per second) through the primary of an induction coil and connecting the terminals of the secondary to the rectifiers. The length of the rectified spark can be increased by putting a number of lamps in series in each arm of the quadrilateral arrangement. Sir Oliver Lodge performed an experiment at the meeting to show the dissipation of fog by electrification. The current from an alternator was passed through the primary of a coil and the terminals of the secondary connected to the rectifiers, 12 lamps in all, three in series in each arm. This arrangement is capable of giving a rectified spark 2in. or 3in. long, the unidirectional nature of which can be proved by passing it through a Crookes or a Röntgen tube. Some magnesium wire having been burnt under a large bell jar to fill it with a cloud of magnesium oxide, the jar was then illuminated by the light from an electric lamp. Passing through the base-piece upon which the bell jar was placed was a conductor which terminated in a point inside the jar. When the terminals between which the rectified discharge was passing were separated and the other end of this conductor was joined to one of them, the electricity streaming from the point into the clouded atmosphere caused an immediate deposition of the magnesium oxide.

Prof. W. E. Ayrton congratulated the author, and expressed his interest in the experiment showing the deposition of magnesium oxide. He pointed out that the combination of four Nodon valves for obtaining a continuous current from an alternating one had been used before. Dealing with the rectifier itself, he said his feeling was that the rectification was due to a difference in the electrodes, and not to any special proximity of two electrodes through the glass, as suggested by Sir Oliver Lodge. There were many cases of rectification—a metal carbon arc, for instance. In this case the explanation of the phenomenon was probably connected with the fact that one electrode was metallic and the other carbon. In the mercury lamp both electrodes were metallic, but the metals were very different from each other. Prof. Ayrton said that Prof. Steinmetz had recently shown him some interesting experiments with mercury arc lamps, resembling in some details the Cooper-Hewitt lamp. There was, however, no choking coil, the starting being effected by an electromagnet capable of separating two tags within the tube, and causing a small arc which started the lamp. There was also no branch lead from positive electrode to the mercury end of the lamp. In his opinion this connection was only a starting device in the Cooper-Hewitt lamp. Prof Ayrton concluded by expressed his pleasure that the administrative duties of Sir Oliver Lodge had not interfered with his keen interest in scientific research.

Prof. H. L. Callendar expressed his interest in the paper and in the experiments shown. In connection with the rectification he pointed out that under certain conditions any vacuum tube would act as a rectifier, illustrating the point by an experiment with an X-ray tube. The phenomenon was noticed by Hittorf 30 years ago and attributed by him to the constriction around the negative electrode.

Mr. W. Duddell said he should like to discuss the rectifying power of mercury lamps. Any two different electrodes in air will rectify to some extent. In the case of two carbons, the diameters of which are as 2 to 1, the resistance between them varies by 5 or 6½ per cent., according as the current is passed one way or the other. With a metal carbon arc it is possible to stop the current altogether. A point and plate will also act as a rectifier. He thought that the condenser arrangement was to facilitate starting, and expressed the opinion that the rectification was due to the temperature of the electrodes and the temperature gradients near them. The temperatures of the mercury and iron in a mercury lamp were very different, and in the case of a point and plane there was a difference of temperature because of the cooling of the plane by radiation. He had also found that the best rectification takes place between electrodes having a high potential difference, and that when using the lamp for practical purposes the presence of impurities improved it by facilitating starting.

Dr. C. Chree pointed out that there was a potential gradient in the atmosphere from the ground upwards which sometimes amounted to 1,000 volts per metre, and was often 150 volts per metre. He asked if this difference of potential between the ground and the tops of high trees would have any effect upon the dissipation of fog.

Sir Oliver Lodge, replying to Dr. Chree, said it had occurred to him that atmospheric electricity must be taken into account, and said it was quite feasible that point discharges from trees might have some effect upon fogs, but not enough. Replying to Mr. Duddell, he said they had found that for high-tension rectification it was necessary to have as good a vacuum as possible, but for lamps working on low voltages it was beneficial to permit a residue of impurities. He said he was still of the opinion that the outside connection assisted the rectification in some tubes by throwing a great strain on the gas near the cathode.

Sir Oliver Lodge then described **"An Arrangement for Driving Mercury Pumps,"** designed by himself and Mr. P. Davies. The apparatus was constructed because the work necessary to make large numbers of vacuum tubes renders it essential to drive the pump hydraulically. The preliminary exhaustion is effected with an ordinary Fleuss pump and the work completed by using a Töpler mercury pump. The reservoir of the pump is suspended from the rim of a 6in. wheel, and is almost counterbalanced by a water-vessel suspended from the rim of a 2ft. wheel fixed upon the same axle. The water-vessel is capable of moving up and down between vertical guides, and mechanism is so arranged that when it reaches the top of the guides a tap is turned and it is filled with water. The increase in weight causes it to descend and raises the pump reservoir. When it reaches the bottom of the guides, a valve in the bottom of the vessel is opened automatically and the water is discharged. The vessel then rises again and the process is repeated. Keyed to the axle carrying the two wheels referred to there is a third wheel, 1ft. in diameter, over the rim of which passes a friction band. The function of this arrangement is to control the upward and downward motion of the water-vessel, bringing it to rest quietly at each end of the journey and yet allowing it to move quickly. There is also a device at the bottom of the guides for keeping the valve of the vessel open until the whole of the water has been discharged. The mercury which overflows from the pump is conducted back to the reservoir, thus giving a circulation of mercury and automatically replenishing the reservoir.

FORTHCOMING EVENTS

FRIDAY, NOV. 20.

National Cycle and Motor Show.—Opening of an eight-day show of cycles, motorcars, and accessories.

SATURDAY, NOV. 21.

Junior Institution of Engineers.—At 2.30 p.m., visit to Orchard Dock, Blackwall, to witness a demonstration of fire extinguishing, etc., by invitation of the Clayton Company.

Ipswich.—At 12.30 p.m., opening of electric generating and tramways undertaking.

MONDAY, NOV. 23.

Society of Arts.—At 8 p.m., Cantor lecture, "The Mining of Non-Metallic Minerals," by Mr. Bennett H. Brough. (Lecture I.)

TUESDAY, NOV. 24.

Institution of Civil Engineers.—At 8 p.m., ordinary meeting. Paper: "On the Distribution of Mean and Extreme Annual Rainfall over the British Isles," by Mr. Hugh R. Mill, D.Sc.

WEDNESDAY, NOV. 25.

Society of Arts.—At 8 p.m., ordinary meeting. Paper: "The Universal Exposition at St. Louis, U.S.A., 1904," by Mr. Geo. F. Parker.

Institution of Civil Engineers.—At 2.30 p.m., Students' visit to the Great Northern Railway underground stations at Finsbury Park.

THURSDAY, NOV. 26.

Institution of Electrical Engineers.—At 8 p.m., ordinary meeting. Papers: "The Testing of Electric Generators by Air Calorimetry," by Mr. R. Threlfall, M.A., F.R.S.; "The Edison Accumulator for Automobiles," by Mr. W. Hibbert.

FRIDAY, NOV. 27.

Physical Society.—At 5 p.m., at the Royal College of Science. Ordinary meeting. Papers: "An Electrical Thermostat," by Mr. Horace Darwin; "On the Occurrence of Cavitation in Lubrication," by Mr. S. Skinner; "A Lecture Experiment in Electrical Resonance," by Dr. W. Watson.

SATURDAY, NOV. 28.

Glasgow Scientific Society.—At 7.30 p.m., ordinary meeting. Paper: "Some Remarks on the Willans Engine," by Mr. J. Herbert Pocock.

NEW COMMITTEES.

ACCRINGTON.—*Electricity, Legal, and Parliamentary*—Aldermen Cunliffe, Hindle, Lee, Rawson; Councillors Bunting, Bury, Jas. Cunliffe, Higham, Langham, W. Lupton, and Slinger.

AYR.—*Lighting*—Whole members of Council; five a quorum; Mr. Young, convener. *Tramways*—Whole members of Council; five a quorum; Mr. James S. Hunter, convener.

BARNSLEY.—*Electricity and Lighting*—Councillor Brady (chairman); the Mayor; Alderman Wilkinson; Councillors Atkinson, Carter, Cotterill, England, Harvey, Kenworthy, Rose, and Wells.

BARROW.—*Electricity*—Aldermen Bradshaw, Lee, Smith, and Townson; Councillors Ashburner, Atkinson, Cox, Dawson, Fisher, Hardy, Hewetson, Taylor, Tootill, Townsend, Wadham, and Young.

BATLEY.—*Electric Lighting, Traction, and Tramways*—Aldermen North and Hirst; Councillors Bagshaw, Childe, Ineson, and B. Turner.

BEDFORD.—*Electrical*—Messrs. Walton, Robinson, Telling, W. Wood, Brogan, and Dickson.

BIRKENHEAD.—*Tramways*—Alderman Cook; Councillors Blaylock, Curphey, Edwards, Evans, Griffiths, Laird, Litwall, H. L. Pearson, Proudman, Snape, Venables, and Cox, and the chairman of the Ferries Committee. *Electricity*—Alderman Lees; Councillors Bennett, Cox, Duckworth, M'Gaul, Nowell, Proudman, Russell, Thomas, Wall, and Watson.

BOLTON.—*Tramways*—The Mayor and Deputy-Mayor; Aldermen T. E. Smith, Harwood, and Nicholson; Councillors Battle, Fletcher, Horner, P. Higson, Maginnis, Panton, Wild (Deane), Witter, Vose, Rostron, and D. Isherwood. *Electricity*—The Mayor and Deputy-Mayor; Aldermen T. E. Smith and Fielding; Councillors Panton, Berry, W. Cooper, Duxbury, Marshall, Rothwell, Clarkson, Gorton, N. Ramsden, and Waddington.

BOOTLE.—*Electric Power and Lighting*—Alderman Brewster (chairman); Councillor Wm. Brown (deputy-chairman); Alderman McMurray; Councillors Bell, W. B. Brown, Carruthers, Clarke, Clemmey, Hanlon, King, Pearson, and Randall.

BOURNEMOUTH.—*Lighting* (to include electric lighting)—Aldermen Lane and Parsons; Councillors Burden, Gunning, Harris, Hunt, C. R. Hutchings, W. E. Hutchings, Jones, Parry-Crooke, Roberts, Robson, Rolls, Street, Youngman. *Telephones*—Aldermen Lane and Parsons; Councillors Abbott, Burden, Gunning, Harris, Hawkes, W. E. Hutchings, Minty, Wilson, Youngman. *Tramways and Parliamentary*—Aldermen Davis, Lawson, Mattocks, Stockley, Webber; Councillors Abbott, Allen Banks, Bell, Beckett, Drake, Frost, M.D., Gunning, C. R. Hutchings, Youngman.

BRADFORD.—*Tramways*—Chairman, Mr. James Hill; vice-chairman, Alderman Enoch Priestley. *Electricity*—Chairman, Mr. G. H. Robinson; vice-chairman, Mr. Tom Lister.

BRIGHTON.—*Lighting*—Councillor Bedford; Alderman Lowther; Councillors Briant, Broadbridge, Carden, Halliwell, Butt-Thompson, Galliers, Holloway, Swift, Blaker; Alderman Botting. *Tramways*—Alderman Stafford; Councillors Carden, Wilson, Blaker, Butt-Thompson, Galliers, Stone, Halliwell; Alderman Sendall; Councillor Swift; Alderman Buckwell; Councillor Holloway. *Telephones*—Councillors Beryl, Black, Carden, Colbourne, Hardy, Jarvis, Lawson, Lintott, Mayston, Pankhurst, Stringer, and Yates.

BRISTOL.—*Electrical*—The Lord Mayor; Aldermen Pearson (chairman), Lowe; Messrs. Hughes (vice-chairman), Lloyd, Elk, Chandler, Dr. Cook, Messrs. Witty, E. Collins, Langford, Perry, and Curle.

BURY.—*Tramways*—The Mayor; Aldermen Ashworth, Fletcher, Parks; Councillors T. Ashworth, W. Ashworth, Battersby, F. Bradley, Hall, Hewart, Hill, R. Kay, Spencer, and Wilde. *Electricity*—The Mayor; Aldermen Dawson and Duxbury; Councillors T. Ashworth, Battersby, Hill, R. Kay, Sanderson, Slater, P. Smith, and Spencer.

DERBY.—*Electric Lighting*—Aldermen Ann, Butterworth, Duesbury, Fletcher, Spriggs; Councillors Brigden, G. Dean, Eaton, Haslam, Shackleton, Wilkins. *Tramways*—Aldermen Butterworth, Duesbury, Fletcher, Spriggs; Councillors J. Dean, Eaton, Gandy, Haslam, Ottewell, Walker, Wilkins.

EALING.—*Electric Light*—Aldermen Green, Tyer, and Kasner; Councillors Hardman, Menzies, Peal, Purvis, and Richards.

EASTBOURNE.—*Electric Light*—The Mayor; Aldermen Pocock and Strange; Councillors Eden, Hillman, Hoadley, Martin, Colonel Mein, Rowe, Simmons, Tinling, and Wright.

GILLINGHAM.—*Electric Light and Baths*—Alderman Barnes; Councillors Holmes, Cornelius, Edwards, Parrick, Lewington, Middleton, and Hunt.

HALIFAX—*Tramways and Electricity*—Alderman Hey (chairman); Councillor Fawcett (vice-chairman); Aldermen Tyson, Booth, Walsh, Crossland; Councillors Ward, Clark, J. Whitaker, Dalton, Stansfield, Brotherton, Alderman, Oates, and Seed.

HAMMERSMITH.—*Electricity and Lighting*—Councillor C. Johnson, chairman; Alderman the Rev. Canon White vice chairman.

HEYWOOD.—*Electricity and Tramways*—The Mayor; Aldermen Hodgkinson, Maden, and Marlor; Councillors Ashworth, Cockerill, Coupe, D. Healey, W. Healey, Ingham, Jackson, Popple, and Smith.

HORNSEY.—*Electricity*—Aldermen Fox and Mackenzie; and Messrs. Grayson, Piercy, Farquharson, S. Smith, J. H. Wilson, and two new members.

HUDDERSFIELD.—*Tramways* (exclusive of the Mayor, 21)—The Mayor; Aldermen Firth, Jessop, Whitehead; Councillors Ainley, Cartwright, Cook, Coward, Dobson, Gee, Lawley, Moore, Oxley, Pogson, Rolfe, Ernest Shaw, Thomson, Alfred Sykes (North), Taylor, Whitworth, Brook, and Aston. *Electricity* (20, exclusive of the Mayor)—The Mayor; Aldermen Hellawell, Calvert, E. Woodhead, Jepson, Whitehead; Councillors Berry, Chatterton, Cook, Dobson, Gledhill, J. Holroyd, Longbottom, Pogson, Priest, Ernest Shaw, Smith, Alfred Sykes (North) Thomson, Whittell, Woolven, Heppenstall, and Hesketh.

IPSWICH.—*Electric Supply and Tramways*—The Mayor; Alderman F. Turner; Councillors S. Brand, Geo. Butcher, S. G. Howe, H. J. W. Jervis, J. Pratt, W. T. Pretty, E. P. Ridley, and Owen Turner.

LANCASTER—*Electricity*—The Mayor; Alderman Smith; Councillors Hall, Heald, Huntington, Oglethorpe, Threlfall, Dixon, Cardwell, Seward, Wright, and Bell. *Tramways*—The Mayor; the ex-Mayor; Aldermen Smith, Huntington; Councillors Hall, Wilson Heald, Threlfall, Towers, Thompson, Kirkby, Seward, and Wilkinson.

MACCLESFIELD.—*Electricity*—The Mayor; Aldermen Brocklehurst, Eaton, Fountain, Mellor, and Savage; Councillors Clayton, Cameron, Heath, Crew, Whitmore, Cross, Isherwood, Bailey, Oldfield, Brown, Wardle, and Staniforth.

MORECAMBE.—*Hackney Carriage, Railway Facilities, and Electric Light*—Aldermen Carleton, Snowden, Wilson; Messrs. Ashton, Bennett, Coulthurst, Miller, Moore.

NELSON.—*Electricity and Tramways*—The Mayor; Aldermen Reed (chairman), Hartley, Greenwood, Hudson, Edmondson, Wilkinson; Councillors Wilkinson, Hargreaves, Whitham, and Smith.

NEWPORT.—*Gas, Electricity, and Water*—Aldermen A. Oldroyd and F. Rhodes; Councillors B. Campbell, R. F. Machell, J. McCann, F. Newsome, A. Pearson, and G. Thorpe.

NOTTINGHAM.—*Tramways*—Aldermen Brownsword, Bright, Ford, McCraith, and Sir John Turney; Councillors Ashworth, Baker, Bellyeald, Butler, Houston, Hunter, Johnstone, and Loverseed. *Electricity*—Aldermen Lambert, McCraith, Sir John Turney, and Woodward; Councillors Ashworth, Cleaver, Elborne, Johnstone, and Palmer.

RIPON.—*Gas and Electric Lighting*—Mayor (chairman); Councillor Watson (deputy chairman); Aldermen Spence and Thirlway; Councillors Boddy, Savill, and Dixon.

SAFFRON WALDEN.—*Electric Lighting*—The Mayor; Alderman Bell (chairman); Councillors Atkinson, Gover, and Tuke.

SALFORD.—*Tramways*—Aldermen Halton, Jenkins, Linsley, and Worsley; Councillors Barker, Barnes, Barrett, Hodgson, Hopwood, Jones, Muir, Shaw, Stringfellow, and Yearnshaw. *Electricity*—Aldermen Frankenburg and Shaw; Councillors Barrett, Hale, Higson, Hill, Hodgson, Jones, Leach, McDougall, Rothwell, Sackville, Taylor, and Wheatcroft.

SOUTHAMPTON.—*Tramways*—The Mayor; Junior Bailiff Andrews; Aldermen Button, Dunsford, Tilling, Bicker-Caarten, Bonner, Dixon, Hancock, Hollis, Jenvey, Line, Willey. *Electricity*—The Mayor; Aldermen Button, Emmanuel, Dunsford; Councillors Aldridge, Bickers-Caarten, Blakeway, Doling, Hancock, Lewis, Tebbutt, Willey, and Wright.

SOUTHEND.—*Light Railways*—Aldermen Brightwell and Tolhurst; Councillors Barker, Campbell, Craig, Hubbard, Martin, Norman, and Roberts.

SOUTHPORT.—*Electricity*—Aldermen Hulme, Unwin, and Vaughan Councillors Ashton, Boyd, Brighouse, Foggitt, Hough, Ingham, T. Jones, H. T. Smith, Travis, and Young.

SOUTHWARK.—*Electric Light* (16)—Aldermen Cannon, Hawkins, and Haynes; Councillors Auton, Bunyard, Cook, Davies, Edwards, Hughes, Newmans Norman, Osbrees, Sharp, Westcott, Morton (Progressives), Chell and Sames (Moderates).

STRATFORD—*Electric Light*—Aldermen Hawkes, Park, and Pearce; Councillors Ballance, Barnard, Everard Tyler, and Winter.

TAUNTON.—*Electric Lighting*—Aldermen Potter (chairman), Lock, Perkins; Councillors Lewis, Norman, Sibley, Van Trump, Webb.

WARRINGTON.—*Electricity and Tramways*—Aldermen Bennett, Bolton, Smethurst, Pierpoint, and Sutton; and Councillors Ellison, John Evans, Pemberton, Tinnion, Wilkinson, Peacock, Craik, Lord, Thornton, and Maginn.

WIGAN.—*Electric Light and Tramways*—Chairman, the ex-Mayor; vice-chairman, Councillor W. Lowe; the Mayor; Messrs. T. Ashton, J. Ballard, J. T. Gee, J. Hilton, R. Leyland, W. Leyland, J. Paxton, R. Richards, S. Taylor, S. Wood, W. R. Deakin, and J. McQuaid.

WORKINGTON.—*Electric Lighting*—Messrs. M'Aleer, Wallis, Milburn, Holmes, Duffield, M'Mullen, Walker, Yeowart, and Kennaugh.

WORTHING.—*Electricity*—Alderman Piper; Councillors Fraser, Gilbert, Morcraft, Norris, Raffety, Tate, and Walter.

PROVISIONAL ORDERS.

The following notices of intended application for provisional orders appear in the *Gazette*:

ELECTRIC LIGHT AND POWER.

Lancashire Electric Power (company); Clitheroe Corporation Lighting; Leicestershire and Warwickshire Electric Power (company); London Electric Lighting (adjustment of areas); Ealing Corporation Lighting and Power; Tynemouth Corporation Electric Light; Northampton Borough Council Electric Light; Hexham Electric Lighting (E. P. Harvey); Walmer Urban District Council Electric Lighting.

TRAMWAYS.

Royton Urban District Council; Crompton Urban District Council; Leek, Caldon, Low, and Hartington Light Railways (above company and North Staffordshire Railway Company); West Ham Corporation.

LONDON TRAFFIC ENQUIRY.

The Royal Commission on London Locomotion again sat at the Westminster Palace Hotel on the 12th inst., Sir David Barbour presiding.

Mr. Andrew Young, valuer to the London County Council, gave further evidence on behalf of the London County Council. He was of opinion that the only economical method of carrying out street improvements in London was by laying-out the projected new streets in such a way that it would not be necessary to acquire a large proportion of valuable property occupied for business purposes. He went on to say that the proposal under consideration was the construction of streets of a greater width than any hitherto projected in London—namely, 160ft.—which must involve outlays of great magnitude. If the proposal were further extended, as he understood it was suggested, so that there should be special means of locomotion by surface tramways, motor, and other fast traffic, and by tube railways, the possibilities for recoupment would not only be increased, but would extend over very large areas of these remoter districts. Questioned as to the proposed new thoroughfare in continuation of the Holborn to Strand improvement—across the Thames, through Southwark, Bermondsey, and Camberwell, to the Crystal Palace—the witness said he had formed an approximate estimate of the cost of acquiring the necessary property. The line of route was 6¾ miles in length, and he estimated the cost at £12,000 000. He had included an area of land 150ft. deep on either side of the proposed thoroughfare, and this would enable the Council to purchase and then sell with the benefit of the improvement after construction. A considerable portion of the £12,000,000 would, no doubt, be recovered by the sale of the surplus property.

The **Chairman** remarked that it had been suggested that it would be advantageous if a general scheme of street improvements to be carried out over a long period of years were laid down.

The witness's comment on this was that if such a course were practicable many advantages would accrue from its adoption, but it would be necessary for the financial success of such a scheme that any plan prepared with a view of future improvements should be treated as confidential, for as soon as it was known that property would be required for public purposes new interests were created for the purpose of obtaining increased compensation.

Sir Alexander Bruce, assistant commissioner of the Metropolitan Police, next gave evidence. He said that owing to the mode of growth of London there was an absence of plan in the construction and arrangement of streets, and no adequate provision had been made for growing needs. There seemed to be but one effective remedy—that of providing subways carrying all pipes, sewers, etc., so that they could be got at without interfering with the surface of the roads. With respect to tramways, he considered that tramway routes and termini had not always been fixed with due regard to the convenience of the public. He particularly referred to the congestion at the Westminster Bridge-road, and said that the Commissioner of Police had endeavoured to get the terminus removed to the other side of York-road. One remedy for such a state of things was to have the termini in by-streets, and another was that the tramway should, instead of stopping as it did now, go off at some by-street, form a loop, put down its passengers, and then come on to the main line.

At the sitting of the Commission the following day the witness resumed his evidence: In summing up, he said that from a public point of view the chief hindrance to a steady flow of traffic was cross traffic. So long as a street had other streets running into it carrying cross traffic, there must be frequent compulsory stoppages, and resulting annoyance and delay. Subways might be provided for pedestrians or bridges, but it was not easy to see how this could be done in the case of vehicles. It was for engineers to say whether or not it was possible. From a police point of view, it would afford more relief than any other remedy.

Superintendent Bantick, D Division, Metropolitan Police, described the kind of traffic in the main streets of that district, and his evidence was mainly directed to this point.

The Commission adjourned.

APPOINTMENTS VACANT.

Engine-Room Attendant. Salary 35s., rising to £2 per week Particulars from the Secretary, South-Western Polytechnic, Manresa-road, Chelsea, S.W.

Shift Engineer, Tunbridge Wells, £100 per annum.

Mains Superintendent, Bexhill Borough Council. Salary, £2; 21st inst. See advertisement in last issue.

Brassfinishers accustomed to switches, arc lamps, the Manufacturing Electric Company, Limited, 11, Red Lion-street, Clerkenwell. See advertisement in last issue.

Assistant Works Manager for lamp factory, Ampere, care of J. W. Vickers, 5, Nicholas-lane, London, E.C. See advertisement in last issue.

Tramways General Manager, Sheffield Corporation, Dec. 1.

Engineering Assistant, used to tramway work, Finchley Urban District Council, £1.5 per annum. Application by Dec. 3:

Electrical Draughtsman, Metropolitan Asylums Board. Salary, £2. 10s. per week. Application by 21st inst.

Clerk, Colchester Electricity Works, 23 d inst.

Assistant Electrical Engineer, Sanitary Commissioners, Gibraltar. Salary, £200 per annum. Applications by Dec. 16. See advertisement.

Under-Foreman, electric repair shop. See advertisement.

LEGAL INTELLIGENCE.

FERRANTI LIMITED.

In the Chancery Division of the High Court on Tuesday Estler Bros. petitioned Mr. Justice Buckley for the compulsory winding up of the above company.

Mr. Buckmaster, K.C., in support of the petition, said his clients were creditors on bills of exchange. The company carried on a large business, and had issued debentures for £100,000. The debenture holders had appointed a receiver and manager, who was carrying on the works, and a meeting of creditors had been called for that day to consider a scheme of reconstruction. He therefore asked that the petition might stand over for a fortnight.

Mr. O. Leigh Clare, for a large number of creditors and preference shareholders, asked that the adjournment should be for one month, because there was a hope of coming to an arrangement by which everybody would be paid in full

Mr. George Henderson, for creditors for £14,500, supported the application for one month's postponement, but

His Lordship thought that at present a fortnight's adjournment would be sufficient.

JANDUS ARC LAMP.

In the Chancery Division of the High Court on Wednesday, Mr. Justice Kekewich had before him a motion arising out of the action Jandus Arc Lamp and Electric Company, Limited *v.* Arc Lamp Company, which was in the list for trial.

Mr. W. Graham said the action was brought to restrain the infringement of two patents by the defendant company. The plaintiff company, for whom he appeared, had been advised that neither of its patents in the form in which they now were could be safely litigated upon, and the motion was for plaintiff company to be allowed to amend its specification.

Mr. Bousfield, K.C., on behalf of the Arc Lamp Company, submitted that, as the plaintiff company could not win on its present materials, the action ought to be dismissed.

In the result, his Lordship granted the application. It was directed that the action should stand over generally.

SPEED OF TRAMCARS.

At the South-Western Police Court on Monday, before Mr. Garrett, an application was made by Mr. Moffat Ford for 10 summonses against the London County Council for driving their electric tramcars along South Side, Clapham Common, at a speed in excess of the legal limit. Mr. Ford stated that he timed the cars on Sunday morning and found that they were travelling at the rate of from 17 to 24½ miles per hour. The summonses were granted.

At a meeting of the General Committee of the National Cyclists' Union, at the Union Offices, Lonsdale-chambers, Chancery-lane, the Secretary reported that he had been in correspondence with the Board of Trade, and had been informed by the Board that the regulations as to limitation of speed are in operation on the following electric tramway systems: London United, Croydon and West Ham Corporation, and East Ham Urban District Council tramways. The regulations provide that each car shall be fitted with a speed indicator and supplementary hand brakes. The speed must not exceed 10 miles an hour except on the south side of Clapham Common, where 12 miles an hour is permitted. At certain parts, where there is much traffic, the maximum speed is reduced to eight miles an hour.

MANSLAUGHTER CHARGE AGAINST A MOTORMAN.

At the Manchester Assizes Alfred Lacey, an electric tram driver, was indicted for the manslaughter of Nathaniel Leather. Leather was in charge of a lurry, and while crossing the line was run into by the car, which, it was alleged, was running at from eight to ten miles an hour. Evidence was given by passengers on the car, some blaming the accused and asserting that he had ample time to avoid a collision, and others stating that the collision was a pure accident.

The **Judge,** in summing up, said the point in question was whether or not the prisoner took notice of the road before him and adopted proper means to avoid a collision. Tramcars, added his lordship, had no more right to the highway than he had, and the drivers must exercise reasonable and proper care. They had not the smallest right to say to people, "at all risks get out of the way," but they must get out of the way themselves if the necessity arose.

After being absent two hours, the jury returned and announced that they could not agree, but at the request of the judge they retired again.

A quarter of an hour later the jury came back, and the foreman announced that they had agreed to a verdict of "Not guilty." Prisoner was therefore discharged.

The **Judge,** addressing the prisoner, said: "I say nothing but this: be more careful in driving these cars in future or you will be here again."

ASSESSMENT OF ELECTRIC LINES

At the West Riding Court, Bradford, an important rating case was heard before the magistrates. It concerned the lines upon which electric cars are run by the Bradford Corporation between Thornbury and Stanningley, and which pass through the areas of the Pudsey Corporation and the Farsley and Calverley District Councils, the case depending on the question whether such lines constitute a "tramway" or a "light railway." The local authorities of Pudsey, Farsley, and

Digitized by Google

Calverley issued a joint summons against the Bradford City Council requiring them to pay the full extent of the rating, amounting to about £31. The Bradford City Council hold the view that the lines are a light railway, and, therefore, exempt from rating to the extent of three-fourths of the total value. A peculiarity of the case is that by an Act obtained by the Bradford Corporation in 1899 the Corporation obtained powers to construct a "tramway" along the main road from Thornbury to Stanningley, but in the same year a syndicate applied and received powers to construct a "light railway" along the same route. As the result of negotiation, the Corporation took over the powers granted to the syndicate, and ultimately elected to utilise them in place of the authority conferred by the Bradford Act, because, for one thing, the syndicate contemplated a double set of rails being laid, whilst the powers obtained by the Corporation's own Act of Parliament provided for only one set. This was one of the points advanced by Mr. Wardle for the Bradford Corporation in proof of the contention that what had been laid was a light railway. Furthermore, the certificate of the Board of Trade given at the time the lines were opened, mentioned that they were constructed under powers granted by the light railway order. The money for laying the lines had, too, been borrowed under the same order, and a separate account was made of the capital expenditure. Once a light railway, it was always a light railway.

Mr. Harrison, for the district authorities, pointed out that this line was indivisible from the whole system of the Bradford tramways. It was not a separate piece of railway worked separately, and as to which separate accounts of receipts were kept. There was no line of demarcation between the Bradford tramways and the so-called light railway which extended from the Bradford city boundary at one end to the Leeds city boundary at the other end. The same cars were run over these lines as were run over the Bradford tramlines, and the electric current was supplied from the same generating station in Bradford. He maintained that in any case the Corporation were not entitled to the three-fourths reduction, because the lines were not used "only" as a railway. Indeed, the case of an ordinary railway did not apply, because here the cars were run on the highway, and the system enjoyed all the advantages of light and the upkeep of the roads. The cost in road repairs was, in fact, much greater now than before.

The Bench came to the conclusion that, although this might be a light railway, the Bradford Corporation were not entitled to the three-fourths reduction upon the rating.

Notice of appeal was given.

SOUTH LANCASHIRE TRAMWAYS.

At the Chancery Court of Lancashire, held at Liverpool on Monday, the case of Greenhouse *v.* the South Lancashire Electric Traction and Power Company, Limited, was heard. The action was brought by certain debenture holders to obtain a decision as to whether resolutions passed at a meeting held on Oct. 7 last were within the provisions of a deed of mortgage dated Jan. 28, 1901, securing the holders of debentures. An injunction was also asked for to prevent the trustees or directors acting upon the resolutions, and for the appointment of a receiver and manager. The point at issue was whether a majority were able to carry as against a minority a resolution which reduced the present first debenture holders to the position of second debenture holders by giving the company power to issue debentures to the amount of £600,000, and place them in front of the present debentures. It was contended that as the system had been built with the money of the debenture holders, it was not reasonable to ask them to forego their priority and take the position of unsecured creditors.

Vice-Chancellor Hall decided against the claim of the debenture holders, and said, although it might seem hard to put £600,000 in front of the existing first mortgage holders, yet persons who invested in the hope of getting 4½ per cent. on the faith of a deed which said that their rights might be compromised or modified by a majority of the shareholders could not come to Court and claim those absolute rights which an ordinary mortgage gave.

The company intimated their willingness to defray the plaintiff's costs.

TRAMWAY TRACK REPAIRS.

The General Electric Tramway Company were summoned at West Hartlepool Police Court, at the instance of the Corporation, on a charge of failing to keep certain portions of the track on the West Hartlepool to Hartlepool section in a proper state of repair.

Mr. J. W. Brown, the borough engineer, said he inspected the track on Nov. 2 and 3, and found that at certain parts within the borough the granite pavement was as much as 1½in. above the rails, whilst at others the rails were considerably below the pavement. The condition of the track was, at the time he inspected it, decidedly dangerous. Since then men had been engaged repairing it, but there were still places where it was in a dangerous condition.

Mr. Tyldesley Jones, who appeared for the defendant company, submitted that that Court had no jurisdiction in this matter. He quoted Section 33 of the Tramways Act, which provides that in any case of difference between a tramway company and the local road authority as to the construction of a track, the matter should be referred to the Board of Trade.

The **Town Clerk** pointed out that in this case it was not a question of construction, but of maintenance and repair, and the Board of Trade had told the Corporation that they must come to that Court to enforce the order.

In the course of the evidence for the defence, **Mr. William John Grier,** chairman of the Hartlepools Electric Tramway Company, said that, as compared with Regent-street, London, Clarence-road, West Hartlepool—one of the places conplained about—was a billiard table.

In the end the Bench found the case proved, and imposed fines amounting to £4, and costs.

WORKMEN'S COMPENSATION ACTS.

A Departmental Committee, appointed by the Home Secretary, is now engaged in considering what amendments in the law relating to compensation for injuries to workmen are necessary or desirable, and as to what classes of employment not now included in the Workmen's Compensation Acts those Acts can properly be extended with or without modification. The committee consists of Sir Kenelm Digby, K.C.B., his Honour Judge Lumley Smith, Sir Benjamin Browne, D.C.L., M.I.C.E., Captain A. J. G. Chalmers, and Mr. George N. Barnes. Mr. R. R. Bannatyne, of the Home Office, is secretary.

COMPANIES' MEETINGS AND REPORTS.

SOUTH LONDON TRAMWAYS.

A meeting of the shareholders in this Company, called by the liquidators, was held at Winchester House on Monday. The object of the meeting was to have laid before it the liquidators' accounts and the hearing of any explanation as to the final disposal of the assets of the Company which the shareholders might desire.

Mr. George Ennis, one of the directors of the moribund company, said the liquidators were able to return a further 6s. 3½d. per share, which, with the £4. 10s. per share paid on March 31 last, would give the shareholders £4. 16s. 3½d. for each £10 share.

A vote of thanks to the liquidators concluded the proceedings.

GUILDFORD ELECTRICITY SUPPLY.

A special meeting of the shareholders in this Company was held last week at the County Hall, Guildford, the chairman (Dr. F. R. Russell) presiding.

A resolution formally agreeing to the substitution of preference shares for the founders' shares, in accordance with the decision of a meeting of the holders of founders' shares held recently, was unanimously adopted. This has been found necessary in order that additional capital, which is needed for the extension of the Company's undertaking, may be raised.

The meeting further authorised the increase of the nominal capital of the Company from £20,000 to £55,000—£25,000 preference shares and £35,000 ordinary shares.

CAPE ELECTRIC TRAMWAYS.

The ordinary general meeting of the shareholders was held at the office, London-wall-buildings, on Wednesday, Colonel Sir Charles Euan-Smith presiding.

The **Chairman,** in moving the adoption of the report, which appeared in our issue for the 6th inst., observed that it afforded the shareholders gratifying proof that their tramway systems at Cape Town and Port Elizabeth continued to exhibit that steady progress as to traffic and revenue which might be regarded as one of the most solid symptoms of stability and success. Notwithstanding the large increase which since the commencement of their working had characterised the traffic and revenue of each successive year, the period under review exhibited a still further increase of £15,837 in their gross revenue, and of 1,245,000 passengers carried, as compared with the figures of the preceding year. It was true that their operating expenditure for the 12 months had proved very heavy, and that the net profit was lower than that of the preceding year by about £15,000, but this was owing to causes against which no foresight on the part of the directors could have protected them. The great strain on the rolling-stock and permanent way from the sudden heavy development of the traffic during the war had rendered a complete overhauling of the permanent way, of the rolling-stock, and of the plant in Cape Town imperatively necessary. All this, in conjunction with the erection of additional power plant and fresh rolling-stock, had had to be carried out at a time when rates for both skilled and unskilled labour and all prices were, as they have since remained, abnormally high. This abnormal expenditure was, however, now gradually diminishing, though much still remained to be done to the permanent way, and these reductions would, it was hoped, further make themselves felt during the current year. In the meantime the directors had the satisfaction of knowing that the Company's plant in Cape Town was efficient and equal to the requirements of the traffic. In Port Elizabeth they had nearly completed the erection of an additional unit in the power-house, and had added to the rolling-stock, bringing it up to the level of the traffic requirements. The increased expenditure on those most necessary items had been provided without the Board having had resource to any measures providing for a further increase of capital. The excess of their expenditure over the original estimates for which funds had been provided had been met from the reserve fund, which now stood at £137,000, and, notwithstanding the decrease in the profit available for dividend, the net result to the shareholders was that they received 12 per cent., free of income tax, on the year's working. With regard to the lease of the Camps Bay tramways, he stated that the directors, in accepting it, were quite prepared for a little loss in the early stages of operating that system, but they were nevertheless satisfied with the terms that were arranged, including as they did the option of purchase by this Company of the Camps Bay tramway system with its parliamentary concession for 50 years. After lengthy negotiations with the Municipality of Cape Town, amended by-laws of that body were now in the hands of the Government for official sanction, whereby some wholesome modifications were made in the oppressive regulations passed in 1901 against overcrowding on cars, which, in contradistinc-

Digitized by Google

tion to the custom prevailing all over the world, absolutely forbade the utilisation of the standing room on the platforms of their cars, and consequently provided a constant source of grievance and dissatisfaction to themselves as well as to the public at large.

Mr. L. Breitmeyer second the motion, which was carried unanimously.

EASTERN EXTENSION TELEGRAPH.

The ordinary general meeting of the shareholders in this Company was held at River Plate House, E.C., on Wednesday, Sir John Wolfe-Barry, K.C.B., presiding.

The **Chairman,** in moving the adoption of the report, said that the gross receipts for the half-year showed a decrease of £18,757. The actual falling off in the receipts from the Australasian traffic was nearly £31,000; but, fortunately, many of the local traffics showed substantial increases, and the loss on exchange had not been sustained this year, owing to the rise in silver and to the revising of rates in silver countries every three months. Working expenses showed an increase of £17,000. The expenses for the maintenance of cables accounted for over £2,000 of that increase, and the North China station, recently opened, for £4,100, but the bulk of the increase was due to the keen and unfair competition which the Company was experiencing at the hands of the British, Canadian, and Australian Governments. Although the privilege of dealing with the public direct was readily granted to private companies in Great Britain, Canada, and other countries, the Governments of Canada, New Zealand, and Queensland had strongly objected to the Company enjoying it in Australasia, and had strongly protested against the Federal Government's decision to extend the privilege to Melbourne and Brisbane. As a result of the protest, the agreement between the Company and the Federal Government still awaited ratification. The competition with the Government was being carried on energetically, and although the Company had to complain of unfair treatment, it had, so far, been successful in retaining its traffic. The Pacific Cable had not helped Australia. The only benefit accrued to the United States, as the traffic with Canada was very small. The Australian traffic was insufficient to support all the lines, and the accommodation would be in excess of the traffic for some years to come. The loss on the Pacific Cable would have to be stood by the taxpayers. At the present time the Company was suffering from two causes in Australia. The first was Government competition, and the second the drought in Australia, which had certainly reduced the volume of business. One cause would remain, but the other, there was every reason to hope, would pass away. The American cable from San Francisco to Honolulu had been extended to Manila, and the Company was now interchanging traffic. The United States, by the arrangement, had obtained access to the Far East, and the Company had obtained another route to Europe. The decision arrived at during the sittings of the International Telegraph Conference, recently held in London, not to make the "official vocabulary" compulsory, ought to put an end, once and for all, to the constant disputes between the telegraphing public and the cable companies as to the admissibility or otherwise of doubtful code words. Under the new arrangement such words, which might be real or artificial, must be composed of syllables capable of pronunciation according to the eight authorised languages, and the words must not exceed 10 letters according to the Morse alphabet. Combinations not fulfilling these conditions would be considered as letter ciphers, and would be charged accordingly—namely, at the rate of five letters per word.

The **Marquis of Tweeddale** seconded the motion, which was carried unanimously.

WEST INDIA AND PANAMA TELEGRAPH.

The ordinary general meeting of the shareholders in this Company was held at Winchester House, E.C., on Wednesday, Mr. Walter Bishop Kingsford presiding.

The **Chairman,** in moving the adoption of the report, said the total receipts showed an increase over the corresponding half of last year of £5,933. That increase was entirely due to a windfall of abnormal traffic which came upon the Company's line in consequence of interruptions to two French companies' cables. Those cables had now been repaired, and since the middle of October that source of revenue had ceased. The political events and possibilities in Panama should certainly mean additional business for the Company's line to Colon. It was the policy of the Board to pay off the arrears of dividend on the first and second preference shares when there were available profits. On Aug. 11 a cyclone swept Jamaica, and the damage to property was enormous. The Jamaican Government's land lines had been wrecked, and the Company's land lines blown down. The Company's cable house at Holland Bay was blown away and the cables dislodged. The Company's clerk at that station had, however, connected the cables up on the beach and saved delay. Such events were continual reminders of the fact that the maintenance of telegraphic communication throughout the West Indian colonies was not an easy business. Considerable trouble had lately been experienced with the cables from Trinidad to Demerara. A large sum had been spent in repairing one cable, and there would come a time when the Board would have to consider whether it would be justified in endeavouring to put that cable in working order. Three sections of the Company's system had remained unrepaired since the Martinique disaster. The repairing ship which endeavoured to repair them had nearly been destroyed, so that the completion had been postponed for more peaceful times. The repairs would be started in a very few days. Efforts were being made to revive the cotton industry in the West Indies, and the successful establishment of an improving industry could hardly fail to bring traffic to the Company.

The report was adopted.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Erith.—The Council invite tenders for the wiring and fitting of premises.

Dorchester.—The Town Council invite tenders for electric lighting. Tenders by Nov. 26.

Preston.—The Borough Council require tenders for switchboards, etc. Tenders by Dec. 12.

Newport (Mon.).—The Borough Council invite tenders for three 50-h.p. motors, etc., by 23rd inst.

Pontypridd.—The District Council invite tenders for the supply of six single and six double-deck electric cars.

Middlesbrough.—Tenders are required by the Corporation for dynamos, boilers, and condensers, by 28th inst.

Brussels.—The Belgian State Railways require tenders for four lots of telegraph poles (specification No. 217). Tenders by Dec. 23.

Maidstone.—The Corporation invite tenders for the construction and equipment of light railways. Tenders by Dec. 7. See advertisement.

Canosa di Puglia (Italy).—The Municipality will receive tenders for installing and working electric lighting for 50 years. Tenders by 30th inst.

Witton (Birmingham).—Messrs Kynoch, Limited, invite tenders for electrical supplies for six or 12 months from Jan. 1, 1904. Tenders by 20th inst.

Hornsey.—The District Council invite tenders for one 300-kw. steam dynamo to be delivered in October, 1904, and another in March, 1905.

Dudley.—The Guardians invite tenders for the supply and fixing of the various appliances for the electric installation to the laundry and boiler house.

Windsor.—The Town Council invite tenders for the supply of electricity or gas for the purpose of public lighting throughout the district for a period of five years.

Wood Green.—The Urban District Council invite tenders for the erection of a power station and the buildings in connection with the Council's electric lighting scheme.

Rangoon.—The Municipal Committee have decided to call for amended tenders for the electric lighting of the town on a continuous-current system. Five tenders were received for the first call.

Batley.—The Town Council invite tenders for the erection of building for refuse destructor. Specifications, etc., may be obtained from the Borough Surveyor, Branch-road. Tenders by 30th inst.

Greenwich.—The London County Council invite tenders for six electrically-driven three-throw boiler feed pumps. Specifications, etc., at the County Hall, Spring-gardens, S.W. Tenders by Jan. 19.

Greenwich.—The London County Council invite tenders for the supply delivery, and erection of four 3,000-kw. generators with exciters. Tenders by 10 a.m. on Dec. 8. See advertisement in last issue.

Wisby (Sweden).—Tenders are invited for a private and public electricity supply estimated to cost 180,000 kroner. Particulars may be obtained from the Director of the Draetselkammaren at the above place.

King's Norton and Northfield.—The Council invite tenders for the erection of car-sheds and waiting room. Tenders by 30th inst. to Mr. Edwin Docker, clerk to the Council, 10, Newhall-street, Birmingham.

Sydney (N.S.W.).—Tenders are asked for the supply of continuous and alternating current meters. Specifications, conditions, and forms of tender are obtainable from Messrs. Preece and Cardew, 8, Queen Anne's-gate, S.W.

London, W.—The Great Western Railway Company invite tenders for the supply, delivery, and erection of water-tube boilers, engines, three-phase generators, and auxiliary plant at Park Royal, near Acton. Tenders by Dec. 7.

Kirkcaldy.—The Corporation invite tenders for one about 400-kw. combined steam-engine and dynamo for lighting or traction (vertical triple-expansion or three-crank compound and multipolar generator). Tenders by Nov. 23.

Cape Town (South Africa).—The Directors of the Cape Town Industrial Exhibition (International) invite offers for lighting the grounds, etc. Tenders to Palmerston House, Old Broad-street, London, E.C. See advertisement in last issue.

London County Council Tramways.—The Council invite tenders for the wiring and fitting for electric lighting of five sub-stations and three car-sheds in connection with the tramways. Tenders by Dec. 5. See advertisement in last issue.

Swindon (Wilts).—The Corporation invite tenders for complete traction switchboard cables, etc. Specifications, etc., may be obtained from Messrs. Lacey and Sillar, 78, King-street, Manchester, and 2, Queen Anne's-gate, Westminster. Tenders by Nov. 23.

Dartford.—The Metropolitan Asylums Board invite tenders for installing a complete system of telephones at the Darenth Asylum, Dartford, Kent. Specifications, etc., may be obtained at the office of the Board, Embankment, E.C. Tenders by 10 a.m. on Nov. 17.

Glasgow.—The Corporation invite tenders for the electric light installation, etc., for Anderston District Library. Specifications, etc., may be obtained from Messrs. Paterson and Stewart, architects, 14, Blythswood square, Glasgow. Tenders by 10 a.m. on 17th inst.

Brighton.—The Council invite tenders for six water-tube boilers; a system of steam, exhaust, feed, blow-off, and suction pipes; and

Digitized by Google

cast-iron storage tanks. Specifications, etc., may be obtained from Mr. Francis J. Tillstone, Town Hall, Brighton. Tenders by Dec. 7.

London, N.—The Hornsey Urban District Council invite tenders for the supply of meters, indicators, and consumers' fuse boxes. Specifications, etc., may be obtained from Mr. Norman Staniland, Electricity Works, Tottenham-lane, Hornsey. Tenders by 30th inst.

Todmorden.—The Corporation invite tenders for one Lancashire boiler, two steam dynamos and balancer booster, two feed pumps and one injector, economiser, surface or jet condenser, switchboard and instruments, storage battery, cable work, and overhead hand crane

Christchurch (New Zealand).—Tenders are invited for the complete installation of electrical tramways, other than buildings Specifications, etc., may be obtained from the Agent-General for New Zealand, Victoria-street, S.W. Tenders by March 17. See advertisement.

Dublin.—The United Tramways Company invite tenders for the supply of general stores, including car fittings, iron, steel, castings, oils, paints, glass, brushes, ironmongery, harness materials, electrical supplies, timber, etc, for year ending Dec. 31, 1904. Tenders by 30th inst.

Barrow-in-Furness.—The Corporation invite tenders for the completion of the electric lighting installation at Hawcoat and Walney police stations and the pig slaughtering hall and lairage at the public abattoirs. Further particulars may be obtained from the Borough Engineer.

Belfast.—The Committee invite tenders for the supply and erection of a complete heating and ventilating system, including steam boilers, heaters, etc., engines, blowers, and electric fans. Tenders by Dec. 4 to Messrs. Young and Mackenzie, architects, Scottish Amicable Buildings, Belfast.

Warrington.—The Cheshire Lines Committee invite tenders for telegraph materials, steel fishplates, creosoted sleepers and crossing timbers, and oak keys. Specifications, etc., can be obtained from Mr. S. Saxon Barton, stores superintendent, Cheshire Lines, Warrington. Tenders by 10 a.m. on 27th inst.

Culiacan (Mexico).—Tenders are invited for lighting the town by electricity: 60 arc lamps of 1,200 c.p. and 110 incandescents of 50, 30, and 16 c.p. will be required. Propositions will be received by letter until Dec. 31 in the Secretaria del Ayuntamiento, Culiacan, where further information may be obtained.

West Ham.—The Education Committee invite tenders for the electric wiring and fittings and for the hot-water heating apparatus required at the Whalebone-lane Higher Elementary School, Stratford, E., and Shipman-road School, Custom House, E., now in course of erection. Tenders by Dec. 14. See advertisement.

Halifax.—The Tramways Committee invite tenders for the execution of the mason, carpenter and joiner, slater, plumber and glazier, and painter's work required in erection of a sub-station at Hipperholme. Specifications, etc., from Mr. James Lord, C.E., Town Hall. Tenders to the Town Clerk by 20th inst.

Madrid.—The Government have issued an order granting an appropriation of 6,000 litres of water per second from the River Tea, in the municipal boundary of Mordariz, province of Pontevedra, for the production, by a fall of 6·40m., of electrical power for industrial uses, for which water power electric plant will be required.

Glasgow.—The Directors of the Caledonian Railway Company invite tenders for the supply of telegraph appliances, etc, and electric lighting material and fittings. Specifications, etc., may be obtained from Mr. Jas. Lorrimer, stores superintendent, Caledonian Railway, Charles-street, St. Rollox, Glasgow. Tenders by 23rd inst.

Handforth (near Manchester).—The Guardians of Chorlton-upon-Medlock Union invite tenders for an electric motor for the new laundry at Styal Cottage Homes, Handforth, near Manchester. Specifications, etc., can be obtained from the consulting electrical engineer, Mr. G. R. Peers, A.M.I.E.E., 16, John Dalton-street, Manchester.

Sydney (New South Wales).—Tenders will be received at the office of the Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 30, for the supply and delivery at the departmental stores, Sydney, of telegraph, telephone, and electric light material. Specifications, etc., may be seen and tender forms obtained at the General Post Offices, Sydney, Melbourne, Brisbane, Adelaide, Hobart, and Perth.

Colombo (Ceylon).—The Government of Ceylon invite proposals from persons willing to enter into a contract for the supply of electrical energy to the various offices, buildings, and premises of the Government, within the Municipality of Colombo, for a term of years commencing on or about Aug. 1, 1905 Proposals must be delivered at the office of the Colonial Secretary, Colombo, by Dec. 1. The *Ceylon Government Gazette* containing above notice may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament-street, S.W.

RESULTS OF TENDERS.

Kingston.—The Council have ordered 500 demand indicators from the Schattner Electricity Company, at an estimated cost not exceeding £800.

Preston.—The Town Council have accepted the tender of Dick, Kerr, and Co., Limited, at £80,592, for the permanent-way construction and overhead equipment of the electric tramways.

Hanley (Staffs).—The Hanley, Stoke, and Fenton Joint Hospital Board have accepted the tender of G. A. Steinthal, Cooper-street, Manchester, at £484. 15s. 6d., for additions to the electric lighting.

Sydney.—The Railway Commissioners require tenders for the supply and laying of 12 miles of electric cable. Particulars may be obtained from the Electrical Engineer, 51, Phillip-street, Sydney, N.S.W. Tenders by Jan. 11, 1904.

Walsall.—The tender of the Walsall Electrical Company, Limited, for the lighting of the Butts-road, Sandwell-street, Cross-street, and Rushall-street sub-stations, for the sum of £21. 10s., has been accepted. Instructions have been given for the economiser supplied by Messrs Green to be insured for the sum of £ 00.

Northfleet (Kent).—The contract for a complete installation of electric lighting and power arc lamps pumping plant etc., with all necessary wiring, for Messrs. Tolhurst and Son's cement works at Northfleet, Kent has been awarded to the British Westinghouse Electric and Manufacturing Company, Limited, London and Manchester

Kilmarnock.—The Electricity Committee invite tenders for work required in connection with the proposed new generating station and tramcar shed: (1) carpenter, joiner, and glazier's work; (2) slaters' work; (3) plumbers' work; (4) plasterers' work; and (5) painters' work. Specifications, etc., from Mr. Robert Blackwood, Market Bridge, Kilmarnock. Tenders by 27th inst.

Glasgow.—For the wiring of various installations, for the Scottish Office of the May-Oatway Fire Appliances, Limited, the successful contractors are the National Telephone Company and McAulay, Clark, and McLaren, for internal wiring. The brigade connections have been secured by the National Telephone Company and by the Glasgow Corporation Telephone Company respectively.

London County Council.—Amongst the accepted tenders for the supply of stores during 1904 we note, under engineers' goods and electrical stores, the names of A. Wilson and Co.; Buck and Hickman, Limited; Mosers, Limited; Jukes, Coulson, Stokes, and Co.; P. and W. Maclellan, Limited; James Gibb and Co.; M. Wilson and Co.; G. Braulik; Stewarts and Lloyds, Limited.

Johannesburg.—The Middlesbrough Chamber of Commerce have received a communication from Mr. Feethams, town clerk of Johannesburg, giving the reasons which influenced the Town Council to accept tenders for rails not of British manufacture for their tramways. Nineteen tenders were received, and of the ten lowest five were for Belgian rails, three for German and two for British. The lowest Belgian tender was £27,382, or with 2½ per cent. import duty £29,102, and the lowest English was £32,525. The Brush Electrical Engineering Company, Limited, it will be recollected, was declared the successful tenderer, some time ago, for steel grooved rails and steel Vignoles rails. The amount of their tenders was approximately £75,000. The tenders are in the market again, and the explanation given by the town clerk is in the following terms: "The reason for fresh tenders being called for is that the Brush Company have exercised their right to withdraw, the time for which their tender was open having expired prior to the acceptance by the Town Council." Further details of the plant appear in another column.

BUSINESS NOTES.

TRACTION.

Gosport.—The laying of the electric tramlines will be started in this district on March 1 next.

Bexley.—Automatic signalling is employed on the new electric tramway system in this district.

Wolverhampton.—The tramway extension up to the Fighting Cocks along Dudley-road has been commenced.

India.—We learn that the Calcutta Tramways Company are competing with Messrs. Kilburn and Co. for the tramway concession at Howrah, in India.

Slough.—The London United Tramway Company propose to apply to Parliament in the ensuing session for powers to lay tramways along certain roads and streets in Slough.

Devonport.—The Corporation Tramways Committee have referred to a sub-committee the question of the construction of a light railway from the borough boundary to Crownhill.

St. Marylebone.—By 30 votes to 29 the Borough Council at their last meeting decided to abide by their previous decision against the construction of tramways in Edgware-road.

Bradford.—During the past year the route length of the Corporation tramways has been increased from 39 miles to 45 miles, while the car mileage has increased by 1,719,898 miles.

Clay Cross.—In reference to the proposed tramway from Chesterfield to Alfreton, it was decided at the last meeting of the Urban District Council to give their general approval to the scheme.

Benwell.—The Tramways General Purposes Committee of the Newcastle Corporation have had an interview with the Urban Council regarding the proposed extension of tramways in that locality.

Baker-street and Waterloo Railway.—This Company will promote a Bill in the next session authorising them to compulsorily purchase lands to enlarge their tunnels for station purposes, etc.

Swansea.—The Board of Trade have appointed Major Druitt to hold an enquiry with reference to the proposed tramway in Oxford-street and Temple-street, when the objections of the tradesmen will be heard.

Bristol.—An electric tramway car in Bristol on Saturday dashed into another car. A driver sustained serious spinal injuries, and a cyclist who was unable to get clear had his left foot completely severed.

Digitized by Google

Wardle.—A special meeting of the Urban District Council has decided to make application to the Board of Trade for a provisional order authorising the construction of electric tramways by the Council.

Derby.—The work of laying down the electric tramways system has commenced. The Alvaston route is the first to be converted, and every effort will be made to get the scheme now in hand completed by the end of March.

South London "Tube."—This line intends to commence the issue of monthly season tickets. It is understood that this action on the part of the company is attributable to the severe competition of the electric tram service.

City and North-East Suburban Electric Railway Bill.—The promoters of this Bill have "reluctantly come to the conclusion that it is to the best interests of all concerned to defer the redeposit of the Bill until the 1905 session of Parliament."

Finchley.—At the last meeting of the Urban District Council the surveyor reported that the contractors were making fair progress with the work of light railway construction in the district considering the extremely wet weather they had had to deal with.

Macclesfield.—The promoters of the Macclesfield and district tramways scheme intend to submit to Parliament in the ensuing session a Bill authorising the carrying out of the scheme which will be identical with the scheme submitted to Parliament last year.

Auckland (N.Z.).—The Auckland Electric Tramways Company have given an undertaking to the City Council that they will not run trams during the church hours on Sundays for the first 12 months after receiving powers, nor thereafter without a special poll of the citizens.

Woking.—The tramways scheme, as finally amended, came before the Urban District Council at their meeting last week, when it was stated that the Council's terms have been accepted by the promoters, who will at once proceed to apply for the requisite Board of Trade order.

Upholland.—A committee of the District Council has been appointed to negotiate with the Wigan Corporation for their consent to pay the cost and expenses to be incurred in connection with an application for a tramway provisional order, and to take over the order when obtained.

Crewe.—The Town Council have withdrawn their consent to a private company proceeding with a scheme of light railways for the borough, and have given notice that they intend to apply to the Light Railway Commissioners in May for sanction to an amended scheme of their own.

Paddington.—A committee of the Borough Council, to whom the matter was referred, recommend the latter to adhere to their resolution of June 9 last dissenting from the electric tramway projected by the London County Council from the Marble Arch, along Edgware-road, to Cricklewood.

Prestwich.—Salford has applied to the District Council for a formal extension of the time within which the Corporation had agreed to construct a tramway to connect the tramway in Bury Old-road with that in Bury New-road. An extension of six months from Aug. 1, 1903, has been granted accordingly.

Gloucester.—An interesting ceremony took place in Bristol-road, just beyond the Nelson Foster Memorial, on Monday, when the Mayor in the presence of a large number of the "City Fathers," ratepayers, and others, commenced the preliminary work in connection with the laying down of the new electric trams.

South Lancashire.—In the near future it will be possible to travel the entire distance between Manchester and Liverpool by tramcar. Already the necessary surveys have been completed by the South Lancashire Tramways Company, and the lines to join up all the towns *en route* will have a total length of over 80 miles.

Elsenham, Thaxted, and Bardfield Light Railway.—The Treasury will make a further grant of £2,000, in addition to the sum of £19,250 already promised towards the expenses of this scheme, on the understanding that this contribution is final, and that the balance of the amount still required will be raised by local effort.

Todmorden.—At a Local Government Board enquiry at Todmorden relative to the application by the Corporation for borrowing powers for electric lighting and power purposes and refuse destructor, it was stated that there was no intention of laying electric tramways at present, but something might be attempted in the way of electric omnibuses.

Hamilton.—At the monthly meeting of the Town Council last week a motion to approach the Lanarkshire Tramway Company for extensions of their lines down Union-street and up to Lowwaters, connecting with the existing tramway route at the Old Cross, was discussed. Eventually the committee were asked to report as to probable cost, etc.

German Rails.—The question of the use of German tramway rails by the Birmingham Corporation came up for consideration at a meeting of the St. George's Ward Conservative Association on Thursday last week, and a resolution was passed to the effect that German rails, even if purchased at a slightly reduced cost, should not be accepted in Corporation contracts.

Manchester.—The proposed new lines of tramways in respect of which powers will be sought next session, as mentioned in our last issue, are as follows: Parker-street and George-street (behind the Manchester Royal Infirmary); Victoria-avenue, between Rochdale-road and Middleton-road (when constructed); Bradford-road (the newly-formed portion); Mill-street, Ancoats.

Leamington.—Communications are passing between the Town Council and the Leamington and Warwick Tramway Company with reference to the system of traction to be adopted in the town. The company are in favour of the overhead trolley, and in the event of this being finally decided on, the Town Council are insisting on a particular form of construction being carried out.

Portsmouth.—At the last meeting of the Town Council the Tramways Committee balance-sheet for the past year was considered, and the committee recommended that the balance on the year's working be called the tramway reserve fund, and that it be left to the Finance Committee to invest. It was stated that there was a balance in the committee's favour of £6,918. The proposition was agreed to.

Greenock.—At the Corporation meeting on Tuesday an amended plan was approved of a "combination" car proposed to be used by the Greenock and Port-Glasgow Tramways Company. In this car there is accommodation for 20 passengers inside and also for five outside seats at each end, a total accommodation for 30 passengers. The cars will be in addition to and not in substitution for the present rolling-stock.

Liverpool and Manchester Electric Railway Project.—It is reported that fresh negotiations are on foot, as the result of which it is hoped to secure the whole of the capital required for the construction of the Manchester and Liverpool Electric Express Railway. It may be mentioned that the expenses in connection with the recently attempted flotation of the Mono Railway Company amounted to something like £18,000.

Newcastle.—The City Council on Wednesday approved a scheme for carrying the tramway system to Blaydon, a village in Durham, the estimated expenditure being £46,000. It was stated that it was proposed to set up a competitive system to the railway company. The Council afterwards, at a special meeting, considered the advisability of promoting a Bill in Parliament for various public improvements, including the construction of additional tramways both in Northumberland and Durham.

Bishop Auckland.—A movement is on foot to secure a system of electric trams for this district, and application is to be made for powers for the construction of lines from Bishop Auckland to Spennymoor, to Eldon-lane, to West Auckland, and to Etherley. Agreement has been given by the local authorities concerned not to oppose the application for powers, as the lines will give easy access to Bishop Auckland, the business centre of a very considerable population, and it is proposed to obtain the money by local subscription.

North-East Lancashire.—A scheme is being prepared for a light railway between Blackburn, Whalley, Burnley, and the intervening townships. Application is to be made to construct a line between Blackburn and Preston, and for a line between Preston and Lytham. If the schemes are carried out in their entirety, there will be an unbroken line of tramways and light railways from Fleetwood and Blackpool on the one hand to Rawtenstall in the Rossendale Valley on the other—a distance of over 60 miles.

Stirling.—At the Town Council meeting on Monday it was reported that Prof. Kennedy's report upon the electrification of the tramway system in the event of its being purchased by the Corporation had been received. The committee dealing with the subject was authorised to enquire as to the conditions upon which the tramway company would part with their undertaking, and also approach the Town Council of Bridge of Allan and the Central District Committee of Stirlingshire as local authorities interested.

Blaydon.—On Friday last a deputation from the Newcastle Corporation paid a visit to Blaydon, where they met a deputation from the local Council with respect to the proposal of the Corporation to extend their tramlines to Blaydon. Plans were submitted showing the suggested route, *via* Scotswood Suspension Bridge, and continuing along Church-street, Garden-terrace, returning by way of Tyne-street. The deputation expressed their intention of commencing the work immediately upon receipt of the necessary powers. The estimated cost is about £47,000.

Wallasey.—A meeting of the Town Council has been held this week, at which it was decided to promote a Bill in Parliament seeking powers for tramway extensions involving a cost of £181,000. The proposed extension is to Wallasey and Poulton. It is estimated the new tramways will cost, inclusive of electrical equipment, £65,000, the road widening and other improvements are calculated to cost £100,000, and the car-shed extensions and additional cars £16,000, the total being £31,000 more than the total expenditure on the three existing routes.

Soothill Upper.—With respect to the electric tramways scheme, it was reported at the last meeting of the Town Council that the circular system from Dewsbury, by way of Leeds-road, Hanging Heaton, and Crackenedge, back to Dewsbury, was not possible because of the enormous expenditure necessary to deal with certain property. It was suggested that trams might be run from Dewsbury, by way of Leeds-road, to Chidswell, but ultimately it was decided to refer the whole subject, including the discussion as to mode of application for an order, to a committee.

Flintshire.—At the fortnightly meeting of the Holywell Rural District Council on Friday, the Clerk stated that a meeting had been held at Mold to consider how far the Flintshire electric tramway scheme would benefit the Halkyn district. At that meeting a suggestion was made that the line, instead of following the main road from Holywell to Northop, should take the top road and go right through the heart of Halkyn district, tapping the lead mines and quarries and affording means for the conveyance of their output. It was decided that this suggestion should be thrown out to the promoters.

Torquay.—Notwithstanding their avowed intention of "abandoning the business," as mentioned in our last issue, the Dolter Electric Traction Company are taking the necessary steps for an application to Parliament for powers in the next session. A representative of the company has returned to Torquay and the posting has taken place of the necessary statutory notices in the streets. In regard to the draft

Digitized by Google

agreement as between the company and the Corporation—some rather stringent clauses in which are believed to have led to the temporary cessation of the negotiations—this document is now under the consideration of the board of directors.

Leicester.—It was announced at the last meeting of the Leicestershire County Council that the negotiations with the Corporation of Leicester respecting the construction and leasing of the two lengths of light railway (the one to Oadby 7 furlongs 5 chains, and the one to Thurmaston 1 mile) had fallen through, as the Corporation were not now prepared to carry out the suggested arrangement which was set forth in the report presented to the Council at the May meeting. The reason for the dropping of the scheme, we understand, is that a substantial increase has been made in the estimate of cost—viz., from £16,000 to £21,000. The report was adopted.

Glasgow.—It was agreed at a meeting of the Parliamentary Bills and Tramways Committee on Monday to apply for a provisional order for several extensions of the electric tramways system. The proposals include the construction of a line from Pollokshaws West to Thornliebank, thence along the Busby-road to Giffnock, and along the Kilmarnock-road from Giffnock, joining the existing system at Pollokshaws East. Another extension is from Maryhill to Bearsden and Milngavie. The question of extending the Thornliebank line to Barrhead is also being considered. The extensions from Crookston to Paisley and the Cambuslang line will be opened for traffic within a few days.

Mid-Cheshire.—In the next session of Parliament powers are to be asked for to take over the Stockport and Hazel Grove system of electric tramways and to extend it from Hazel Grove on to Macclesfield by way of Adlington, Poynton, and Butley, skirting Prestbury. The system will run on to Broken Cross at Macclesfield. and it is proposed also to establish an electric car system in that borough. The present line from Stockport to Hazel Grove is four miles in length, and under the new scheme 14 miles will be added. If the scheme is carried out, there will be a practically continuous line of tramway from Manchester to Macclesfield, through some of the prettiest of the Cheshire country.

Bingley.—At the last meeting of the District Council it was reported that a representative of the company promoting the Mid-Yorkshire tramways scheme had been in negotiation with the Council with a view to the extension of the period during which the Bingley portion of the tramways is to be worked by the company. The Act fixes the period at 30 years, and the Council were asked to extend the time to 42 years. The Finance Committee recommended the Council to extend the lease to 35 years, on the understanding that the construction of the Bingley portion of the line should be taken in hand in the early part of next year, and the line should be laid as far as the bottom of Morton-lane. This course was agreed to.

Cardiff-Penarth Railway.—The Penarth Tramway Syndicate will apply in the next session of Parliament for a provisional order to enable them to construct a tramway line between the Grangetown Bridge and the post office, Penarth. The line will be a single one with passing places, and the cost, including the widening of the road at Cogan Hill and purchasing the whole of the thoroughfare, now vested in Lord Bute, is roughly estimated at about £100,000. Before the proposal comes under the consideration of a Parliamentary Committee, negotiations will be opened by the syndicate with the Cardiff and Penarth Councils, whose co-operation and support, it is hoped, may on certain conditions be secured.

Yarmouth.—On Tuesday a special meeting of the Town Council decided to promote a Bill in the next session of Parliament to empower the Corporation to make and maintain tramways within and without the borough, and particularly across St. Peter's-road, along Blackfriar's-road, Camden-road, across Queen's-road, along Admiralty-road, Barrack-road, South Denes-road, Caister-road, Regent-road, Hall Quay, the Haven Bridge, Bridge-road, Southtown, Southtown-road, Lowestoft-road, Feathers Plain, Baker-street, the Plain, Pier Walk, Pier-road, and the road on the north of the Gorleston Beach Gardens; to empower the Corporation to construct a transporter bridge across, and a subway beneath, the Haven, and for other purposes.

Additional Traffic Returns.—Anglo-Argentine, £1,984 increase; Barcelona Ensanche y Gracia, £136 increase; Barcelona, £7 decrease; Brisbane, £99 increase (month of August, £11,736, increase £294), British Columbia Electric (month of March), gross earnings £10,352, net income £2,659; Buenos Ayres and Belgrano Electric, £307 increase (month of October, £14,055, increase £1,002); Calcutta, £384 increase; Cape Town (month of October), receipts £16,229, expenditure £9,044; Isle of Thanet Electric, £46 decrease; Lisbon Electric (month of October), receipts 93,725 milreis, expenses 50,350 milreis; Mexico Electric (month of August), receipts £48,600, expenses £27,900; Perth Electric, £170 increase; Port Elizabeth (month of October), receipts £3,972, expenditure £2,879.

Plymouth.—The Borough Council are considering the expediency of an application to the Board of Trade for a provisional order empowering the Corporation to construct and maintain four short lines of tramway. The first three lines are in connection with the new road which is being cut from Old Town-street, through Garden-street, and into Tavistock-road. The proposed fourth line is from the boundary of the borough in the Saltash-road at Pennycomequick, up through Caprera-terrace, Torrington-place, and North road. The greater portion of this is already laid for horse traffic, but has not been used for several years. It is proposed to electrify the system, and by this means join up the Devonport and district trams at Stuart with the Corporation trams to Compton, and at the other end to the other Plymouth centres and termini.

Ipswich.—An inspector of the Board of Trade will visit the town to-day (Friday) for the purpose of inspecting the new electric tramways, and it is hoped that sanction will be given for the public opening to take place on the following day. The Electric Supply and Tramways Committee report that the by-laws made by the Council on Aug. 12 last have been allowed by the Board of Trade, and are now in force in the borough. Having regard to the trolley wires, which have now been placed in many highways in the borough, the committee are of opinion that it is advisable that the Council should take the necessary steps to adopt Part 2 of the Public Health Acts Amendment Act, and so be in a position to exercise control and supervision over any wires or apparatus which private persons or companies might desire to put up above, along, or across any street in the borough.

Preston.—The tender of Messrs. Dick, Kerr, and Co. for the permanent-way construction and overhead equipment of the new electric tramways again came up for acceptance at the meeting of the Town Council on Thursday last week. It will be remembered that at the previous meeting the matter was referred back to committee on account of some misapprehension as to who were to be the sub-contractors for points and crossings. Last week it was stated that the specification included British and American rails, but out of the total sum of £80,592 £77,500 odd would go for British material and British labour, while only £3,000 worth of material would come from America. Messrs. Dick, Kerr, and Co. have further agreed to sublet a portion of the special work included in the £3,000 to a British firm and part to the Lorain Company, the American firm. On this understanding the tender was accepted.

London United Tramways.—A new Bill is to be promoted by the London United Tramways Company in the next session of Parliament. The company propose under the Bill to secure powers to construct new tramways in Middlesex, Bucks, and Surrey, to obtain special provisions as to compensation for lands taken, and to extend the time for compulsory purchase of lands and for completion of authorised tramways. The proposed new lines are intended to form an extension of the company's system in the Brentford, Hounslow, and Ealing districts, and to continue the tramways into Bucks. The following parishes will be served by the new lines: East Bedfont with Hatton, Stanwell, Feltham, Ashford, Staines, Hardmondsworth, Slough, Farnham Royal, Burnham, Taplow, Hitcham, Colnbrook, etc. The scheme involves extensive street widenings in Richmond, Kingston, and Wimbledon particularly.

Dumbartonshire.—The Electric Supply Corporation, Limited, have a scheme for laying down a system of tramways in Dumbartonshire. The company have obtained a lease from the Corporation of Dumbarton for the electric lighting of the burgh, and last session, by consent and under agreement with the Town Council, promoted a provisional order for the purpose of laying down electric tramways within the burgh. This order was passed by the Parliamentary Commissioners at their sittings in July last, and the Bill to confirm same has also passed the committee stage of the House of Commons. In ordinary course, therefore, it will receive the Royal assent early next session. The scheme which is now proposed is of two parts. The first of these will connect the eastern terminus of the burgh tramways with the extension of the Glasgow tramways to Clydebank, and the second will extend the burgh tramways to Balloch.

The Black Country.—The work of electrically equipping the tramways which run through Oldbury to Smethwick, Birmingham, and West Bromwich is being pushed forward rapidly, and it is expected that in a short time a complete service of cars will be running. The section forms part of the circuit by which it is proposed to connect the lines of the old South Staffordshire Tramway Company, which pass through Wednesbury, West Bromwich, and Handsworth to Birmingham, and those of the Birmingham and Midland Tramway Company, which run from Dudley, through Oldbury and Smethwick, to Lionel-street, Birmingham. Already there is a service of cars on the Spon-lane and Bromford-lane routes, and when the junctions at Oldbury Market-place and Spon Croft are finished an important step towards the completion of the system of tramways by which the British Electric Traction Company intend to link together all the large towns in the Black Country with Birmingham will be accomplished.

Llandudno.—At Tuesday's meeting of the Urban District Council the Light Railway Committee reported that they had, subject to the Council's approval, agreed with the light railway company in the event of the Colwyn Bay Council obtaining an injunction restraining the Llandudno Council from supplying electricity to the company outside the Llandudno area, to accept £750 instead of £1,000 as the minimum sum to be paid by the company in any one year. The company having written to suggest that, in the event of any other authority than Colwyn Bay obtaining a similar injunction, the minimum be further reduced to £500, the committee replied that they felt they were restricted from further discussing the question whilst the supplementary agreement they were asked to vary remained unchanged, and suggested that if the company were desirous that such agreement should form the basis for further negotiation they would take immediate steps to effect an exchange. The report was confirmed.

Hammersmith.—The Borough Council have received notice from the London County Council stating that that body has decided to introduce a Bill in the next session of Parliament for powers to construct tramways (amongst others) from Shepherd's Bush-road, along Netherwood-road, Westwick-gardens, Richmond-road, Holland Park-avenue, High-street, Notting Hill, and Bayswater-road, to a point near the Marble Arch. A letter has been received from the Board of Trade, dated the 4th inst., transmitting a copy of the revised regulations it has made with respect to the use of electrical power on the London United Tramways and Light Railways, in the form in which it is proposed to issue them in the next few days. The regulations are based on those at present in force, the principal alterations being with regard to the limit of speed at which the tramcars shall be driven in certain specified streets. The Hammersmith Council are of opinion that advantage should be taken of the revision of the regulations by endeavouring to obtain an addition to No. 8, so as to provide that conspicuous notices shall be fixed on the bridges under which the tramcars pass cautioning passengers on the cars against rising from their seats or standing upright when approaching or passing under

Digitized by Google

bridges. A representation is to be made to the Board of Trade to that effect.

Johannesburg.—Contracts are about to be awarded for the power-house, equipment, etc., for the extensive electric traction system to be constructed in Johannesburg, South Africa. There are two sets of specifications, one calling for gas-engines and the other for steam-engines to operate the road. The boiler capacity of the plant will be somewhat over 10,000 h.p. The specifications call for a gas plant capable of gasifying 7½ tons of coal per hour, with coal conveyor, cleaning and cooling plant, and accessories; four gas-engines, each to drive a 1,350-kw. dynamo; three gas-engines, each to drive a 650-kw. dynamo; three gas-engines, each to operate a 675-kw. two-phase alternating-current generator; two motor-generators, each consisting of a 250-kw. two-phase alternator; two dynamos of 150 kw. capacity each; and two 450-kw. dynamos. The specifications for the steam generating plant comprise water-tube boilers of 6,750 kw. capacity, with conveyors, automatic stokers, economisers, condensing plant, engines or turbines, electric generators, motors of before-mentioned sizes. *South African Exports* states that the contracts will be divided between the General Electric and Westinghouse interests in America.

Tottenham Court-road.—One result of the triumph of the Progressives at the recent borough elections in London will probably be the settlement of the Tottenham Court-road tramway difficulty. The County Council desire the extension of the tramway from Euston-road to the Holborn end of Tottenham Court-road, but the Moderates of the late St. Pancras Borough Council resisted this proposal. The County Council have submitted their scheme to the new Council which, the *Daily News* anticipates, being Progressive, will discuss it without any constitutional animosity to trams or to the County Council. Whether this is so or not, we are glad to be able to state that the Borough Council, at their meeting on Wednesday night, reversed the policy of the late Council, and adopted by 36 votes against 20 a resolution giving statutory consent to the construction of the tramway in question. There was an addendum to this declaring that in giving their consent the Borough Council had regard to the views repeatedly expressed by the County Council to the effect that the widening of Hampstead-road and the construction of the tramway along Tottenham Court-road must be considered in conjunction, and that the Borough Council accordingly sanctioned the tramway in the faith that the County Council would at once proceed to put in force the powers granted by the London County Council (Tramways and Improvements) Act, 1902, for the widening of Hampstead-road at the southern end, towards the net cost of which the Borough Council agreed to contribute one-eighth.

East Cheshire.—A new scheme for supplying East Cheshire with electric tramways is on foot. It is proposed to construct a line (10 miles east of Manchester Town Hall) connecting the Manchester, Ashton-under-Lyne, Oldham, Stalybridge, Mossley, Dukinfield, Denton, Hyde, and Stockport electric tramways with the Glossop and Hadfield electric tramways and with the Great Central Railway Company's main line to Sheffield, Leicester, and London at Broadbottom Station, Mottram. A syndicate has been formed for the purpose of obtaining powers under the Light Railway Act, 1896, to carry out a system with Mottram as a centre. It will have a total length of about seven miles, and will provide intercommunication between the towns of Stalybridge, Hyde, Mottram, Broadbottom, Glossop (at Woolley Bridge), Hollingworth, and Tintwistle. The system is divided into three sections—first, Stalybridge and Hyde to Mottram, Hollingworth, and Glossop (Woolley Bridge); secondly, Mottram to Broadbottom; and thirdly, Hollingworth to Tintwistle. The cost of the construction of the complete system is estimated at about £80,000, inclusive of the cost of erecting a power station for generating the electricity. It is, however, not expected that it will be necessary to erect a generating station, as it is probable that power will be obtained from one or more of the adjacent local authorities or other companies supplying power. In the latter case the estimated cost of construction would be reduced by about £10,000. The local authorities concerned have been approached, and, it is stated, are favourably disposed towards the scheme. The capital of the company will be £80,000, with power to issue debentures for £20,000.

Hayling Light Railway.—Colonel C. F. S. Boughey and Mr. Henry Alan Steward last week conducted an official enquiry at the Town Hall, Portsmouth, with reference to the proposal to construct a light railway from the existing terminus of the Portsmouth Corporation tramways to the point where the ferry now goes over to Hayling Island, and where it is proposed by a syndicate to construct a transporter bridge across the Langstone Harbour channel. Mr. Balfour Brown, K.C., on behalf of the promoters, sketched the company's proposals. He pointed out that at present Hayling either had to be reached by means of a ferry, or by rail *vid* Havant, which meant a journey of 14 miles, which occupied times varying between 53 minutes and 1½ hours. Portsmouth had a population of 200,000 people, and Hayling had a population of 1,700. The transporter bridge was similar to those which had been constructed at Rouen, at Runcorn, which would be opened in March, and at other places. It would offer no obstruction to the waterway. The cars would be worked by electricity, and the conveyor would easily be carried backwards and forwards by the same power. Most of the landed proprietors in Hayling Island were in active support of the scheme. The Portsmouth Corporation, which was an interested party, because their tramways would connect with the proposed light railway, expressed the opinion that it would be a good thing for the town, and had passed a resolution in favour of the scheme. At the same time there were one or two points to be adjusted between the Corporation and the promoters. Mr. Eady, M.I.C.E., who, with Mr Wilberforce Cobbett, of Fareham, is acting as joint engineer to the scheme, said there would be no engineering difficulties. The cost was estimated at about £63,000, including £30,000 for the bridge. Mr. Webster, C.E., gave similar evidence, and Sir William Dupree, ex-mayor of Portsmouth, stated that there was a great need for the bridge, which would provide another ready means of exit from Portsmouth and Southsea. After consultation Colonel Boughey intimated that the Commissioners considered that a public case has been made out, and they were prepared to grant the order asked for.

Rail-Welding at Glasgow.—The Corporation of Glasgow have arranged with the Lorain Steel Company, of America, to carry out the electric welding of their new lines to Paisley and Cambuslang, and also a few short extensions within the city. The distance from Crookston to Paisley is about two miles, and the Cambuslang extension is about the same length. The Lorain Company have also arranged to weld the rails on a portion of the old track. This work is being carried out when the cars are off, between 1 and 5 a.m. The total number of joints to be welded under this contract is about 2,000, the Corporation reserving the power to have up to another 1,000 joints welded. This is stated to be the first trial in Europe of electrically welding rail joints, and much interest is being taken in the process by tramway managers and engineers. On Friday the members of the Tramways Committee of Glasgow visited the scene of operations. The process consists in welding to the web of the rails two rolled-steel splice bars, the projections on which are peculiarly adapted to the purpose of securing a weld between the bars and the rail web. The joint is made in three welds—two outside welds for the purpose of tension; the central weld, which is directly at the union of the rails, for vertical stiffness. The central weld being made first, the bars are heated at the middle and elongated before the ends are welded. On cooling, the contraction of the bars exerts a powerful force to bring the abutting rail ends together. The smallest opening is thus closed, leaving practically no joint at all. The apparatus is mounted on trolley cars of convenient size. A sand blast for cleaning rails and bars precedes the welder. The welder itself consists of an alternating-current transformer, having for its secondary winding a single loop of copper of large cross section, the terminals of which engage the bars on either side of the rail. The terminals are operated by hydraulic pressure. A rotary converter takes the current from the trolley and changes it to an alternating current. Flexible cables connect with the welder transformer. At 500 volts about 250 amperes are taken. This is again transformed to the welding current of about 5 volts and 25,000 amperes. The current is on about two minutes at each weld, and it takes from 12 to 15 minutes to complete a joint. After the metal is brought to a welding heat the current is cut off and the weld, while cooling, is confined under a pressure of about 37 tons. This prevents any deterioration of the metal, and results in a remarkably tough weld, which is not equalled by any other known method of welding. After the welding is completed a surface grinder grinds the head of the rail to a true surface. So far the trials at Glasgow have proved quite satisfactory. In the same city shortly the Thermit process of welding joints will be tried. The experiments will be conducted by the Corporation staff.

London County Council.—Chief discussion at the meeting of the London County Council on Tuesday centred round the question of purchasing the London Southern Company's tramlines from Vauxhall to Camberwell-green and West Norwood. The Highways Committee brought up a supplementary report to that given in our last issue, showing that they have still further considered the matter in the light of reducing the capital cost by adopting the overhead trolley instead of the conduit system. The amount of street widenings could be reduced to a minimum in the case of the employment of the former system throughout. With the conduit system the expenditure in respect of street widenings would be extremely heavy, amounting to about £384,000, which, added to the cost of acquisition and reconstruction, would give a total gross outlay of nearly £700,000, or a total charge to the tramways account of about £430,000. The proposal of the committee now is that the trolley system should be employed on the lines between Stockwell and Camberwell-green and Norwood, and the conduit system only on the line from Stockwell to Vauxhall. This scheme would involve a total gross cost for street widenings of about £129,350, or, after deducting the value of the surplus lands, an estimated net cost of £121,350, while the cost of acquiring the undertaking and reconstructing the lines, including the provision of cars and car-sheds, sub-stations, and all incidental works, is estimated at about £254,000. It is proposed that the net cost of the street widenings should be borne, as regards one-third, by the local authority concerned, the Lambeth Metropolitan Borough Council, the remainder being charged in equal proportions to the tramways account and the account of the improvement. The total expenditure involved therefore, so far as the tramways are concerned, is about £295,000, and the whole outlay will be about £375,000. By the adoption of this plan it will be practicable to arrange for a through service of cars on the conduit system to be run between Clapham-road and Vauxhall, and ultimately over the new Vauxhall Bridge, when completed, to Victoria Station. The committee are of opinion that the lines, when reconstructed in this way, will prove to be self-supporting and there can be no question that they will add very materially to the convenience of the travelling public. The meeting discussed the above proposals at length, the main debate turning on the present depressed state of the money market. Mr. Benn, replying on the debate, stated that the Highways Committee had every expectation of the new line paying 7 per cent. on the investment. A motion to call a statutory meeting of the Council to decide for or against the purchase was ultimately agreed to, with four dissentients, and in the meantime the various local authorities interested will be invited to express their views on the scheme. The meeting afterwards voted a sum of £90,000 for the purchase of rails for the electrification of tramways north and south of the river, the steel market being now very favourable for the purchase. Details of the proposed purchase appeared in our last issue. Owing to the withholding by the local authorities interested of their consents to the construction of certain new lines of tramways, the Council

Digitized by Google

decided not to proceed further with the following proposals: Southwark-street (London County Council tramways), at Hop Exchange corner, *via* Stamford-street, York-road, and across Westminster Bridge-road to Lambeth Palace-road; Shepherd's Bush-road, *via* Westwick-gardens, Netherwood-road, Richmond-road, Holland Park-avenue, High-street, Notting Hill, and Bayswater-road, to a point near Marble Arch; Battersea Park-road (London County Council tramways), *via* Battersea Bridge-road, Battersea Bridge, and Beaufort-street, to King's-road, Chelsea; Tooting High-street (authorised London County Council tramways), *via* that thoroughfare to the new county boundary. In connection with the construction of tramways in St. John-street and St. John-street-road, in North London, Messrs. J. G. White and Co. are to proceed at once with the laying of about 160 yards of the proposed lines at the same time as some paving works are being carried out. The estimated expenditure for which the committee asked authority is £2,650. Next week the Council will consider a proposal to spend £35,000 for the rebuilding of the car-sheds at Streatham.

LIGHTING AND GENERAL.

Walsall.—The total number of consumers supplied on Oct. 31 last was 296.

Dartmouth.—The lights on the Embankment are being increased from 50 c.p. to 100 c.p.

Kingswinford.—It is proposed to add 20 25-c.p. lamps to the public lighting in the rural district.

Walmer.—The Urban District Council of Walmer intend to apply for an electric lighting provisional order.

Mirfield.—The Yorkshire Electric Supply Company will be ready to supply electricity by the 1st of next month.

Lowestoft.—The resident electrical engineer is preparing an estimate for the lighting of Denmark-road by electricity.

Exhibition.—It is proposed to hold an exhibition of telegraphy and telegraphic apparatus in Copenhagen in February.

Islington.—Low-tension distributing mains are to be laid in Holloway-road and Hornsey-road at a cost of £118.

Pembroke (Dublin).—The Urban District Council will apply for sanction for £20,000 for electric lighting extensions.

Taunton.—Mr. Sharpe, the assistant electrical engineer, has entered upon his duties. It has been arranged to extend a cable.

Morecambe.—The Electric Light Committee have been requested to make arrangements for the more economical lighting of the borough by arc lamps.

Personal.—Mr. Sidney H. Rhodes, of Morecambe, has been appointed assistant electrical engineer at the Greenhill electricity works, Oldham.

Longford (Leinster).—The Town Council are consulting Mr. McAndrews, of Dublin, on the advisability of adopting electricity for lighting purposes.

Gravesend.—On Saturday night the supply of current failed, but was restored after 10 minutes. All the lights went out and the trams were at a standstill.

Acton.—The Urban District Council have decided on a site for the electricity works at Bradford Park, and have appointed Mr. W. H. Trentham consulting engineer.

Byrnmawr.—The Urban District Council have decided to apply for a provisional order authorising them to supply electric light throughout the urban district.

Leek.—The Electricity Committee have received 70 applications for the appointment of resident engineer, and have selected a short leet of four to attend before the committee.

Todmorden.—Major C. E. Norton has held an enquiry into the application of the Corporation to borrow £21,274 for the purposes of electricity works and £6,000 for a refuse destructor.

Wisbech.—The Town Council have asked Messrs. R. Hammond and Son to visit Wisbech to report upon the subject of electric lighting within the borough, and generally to advise the Council.

Clydebank.—The Clyde Valley Electric Power Company intend to apply for power to provide a supply of electricity for public and private purposes in certain districts, including the burgh of Clydebank.

Wimborne.—The Southern District Electrical Corporation are applying for a provisional order giving them powers to supply the district with electricity. The Council will take no action in the matter.

Morley.—Mr. J. E. Ellis, electrical engineer, in his last report states that the output of electricity during the month ending Sept 30 was 11,679 units, against 8,929 in the corresponding month of last year.

Partnership.—Mr. A. Higgins and Mr. S. Griffiths have entered into partnership to carry on the business of electrical engineers and contractors at 4, Albany-street, Regent's Park, N.W., under the name of Higgins and Griffiths.

Bristol.—Mr. Yabbicom, in his last report, refers to the extension of electric lighting in West-street, Bedminster, and St. Paul's-road and Tyndall's Park-road, Clifton, where many gas lamps will, therefore, be discontinued.

Woolwich.—The Council have informed Major-General Jelf, governor of the Royal Academy, that they are willing to render all facilities possible, and to extend the electricity mains to meet all the further requirements of the academy.

Shildon.—The Urban District Council have decided to obtain a writ claiming specific performance of the agreement and drawings, and also an injunction for restraining the local electric lighting company obtaining current from any other company.

Hammersmith.—Since the last Council meeting 37 additional consumers have been connected, representing a maximum of 1,467 8-c.p lamps; 11 consumers have been disconnected, and the present number of consumers now taking current from the mains is 1,345.

Maidenhead.—Several additions to the public electric lighting were agreed to on Monday. The area of the Council's provisional order will include the parishes of Taplow, Hitcham, Burnham, Cookham, and Bray. There are now upwards of 10,200 8-c.p. lamps applied for.

Frome.—The Urban District Council intend to apply for sanction to borrow £7,100 to carry out the suggestions contained in a report by the Council's consulting electrical engineer, Mr. F. H. Medhurst, with regard to the extensions of the cables and the alteration in the site of the cooling tower.

Finchley.—Councillor Martin has retired from the Electrical Committee owing to pressure of other duties. A mains extension, costing £350, to supply 90 houses has been agreed to. The committee are considering an application from the East Barnet Valley District Council for supply in bulk.

Oban.—The Lorne Combination Poorhouse authorities have asked the engineer to make an inspection of the wiring of the poorhouse, and to certify its completeness. The Town Council, however, do not see their way to let the engineer undertake such work. An extension of cable has been agreed to.

Worksop.—The Urban District Council are making several small extensions and have decided to obtain the following supplies: 500 yards of 30-ampere three-core cable; 50 yards of 250-ampere twin-concentric cable; 50 yards three-core pilot wire; three additional connecting boxes; two spare tubes for economiser.

Torpoint.—Mr. J. Enright's report as to the establishing an electricity supply in the district shows that the cost of an installation as suggested would be about £7,000, and would supply 1,500 8-c.p. lamps alight at one time. Up to the present time, as a result of the canvass of the town, only 500 lights have been applied for.

New Issue.—The Montreal Water and Power Company are issuing £70,000 4 per cent. prior lien gold bonds in registered bonds of £100 each, being part of the total authorised issues of such bonds, ranking *pari passu* to an agregate of £500,000. Messrs. Coates, Son, and Co. are authorised by the company to receive subscriptions.

Llandudno.—The Urban District Council on Tuesday decided to reduce the discount allowed on payment of charges for the supply of electricity from 5 per cent. to 2½ per cent. The prices for current were rearranged as follows: flat rate, 5½d. per unit; maximum demand rate, 6d. and 2d.; where minimum of 15,000 units is consumed, 4½d. per unit.

Wishaw.—In consequence of a report from a committee which recently interviewed the agents of the Clyde Valley Electrical Power Company, Limited, regarding the terms on which the latter were prepared to supply the burgh with power in bulk for lighting and motive purposes, the Council have resolved to apply to Parliament for a provisional order

Dudley.—For the six months ending September last the number of units of electricity generated at the Corporation power station was 600,040. In the corresponding period last year the number was 456,896, or an increase in the six months ending September last of 183,178. The extra monetary value compared with the six months last year amounts to £1,300.

Caerphilly.—The District Council have secured consumers for 2,720 8-c.p. electric lights in Caerphilly, Aber, Senghenydd, and Llanbradach. It would require a consumption equal to 2,000 8-c.p. lamps to ensure the electric light scheme being a financial success. It is proposed to charge 6d. per unit. On Tuesday it was decided to proceed with the order forthwith.

Sales of Plant.—Particulars of a nearly new complete electric lighting plant to be sold by tender by Mr. Ernest Pennington, auctioneer, Railway Station, Richmond, Surrey, will be found in another column, as well as details of a sale by Messrs. Weatherall and Green, 22, Chancery-lane, of plant and stock, comprising the complete equipment of an incandescent electric lamp factory.

Batley.—An enquiry has been held into an application of the Town Council for sanction to borrow £5,000 for the extension of cables for the lighting of the populous districts in the borough. The Corporation have already received sanction to loans for electric lighting purposes of £25,402, of which amount £15,007 have been actually borrowed, leaving unexhausted borrowing powers of £10,334.

Gosport.—At the last Council meeting a letter was read from the Board of Trade with reference to the electric light. It stated, as far as the Board could ascertain, no steps had been taken to carry out the works. The Clerk reported that he had written to the secretary to the Portsmouth Street Tramways Company, who have the work in hand, but no reply had been received. The letter was referred to the Roads and Works Committee.

Harrogate. Two new high-tension concentric trunk mains are to be laid, and tenders invited by advertisement for the work. Extensions to switchboard are to be carried out by Messrs. Ferranti at a cost of £250. Consumers who have electricity meters will now have the same rent free in future. The borough surveyor's plans of proposed extensions to electric light station have been approved, and tenders are to be obtained for carrying out the work.

New Addresses.—The City address of Mr. E. Kilburn Scott, M.I.E.E., A.M.I.C.E., is 13, St. Helens-place, E.C., where he is associated with Messrs. Harper Bros. and Co. in the engineering work of the North Wales Power and Traction Company, the Bath and Sunderland District Electric Tramways, etc.—J. Hopkinson and Co., Limited, Huddersfield, have extended their business, and have now offices and depôts at 41, Bothwell-street, Glasgow, and Royal-buildings, Park-place, Cardiff.

Digitized by Google

Yorkshire Electric Power Co.—The first generating station of the Yorkshire Electric Power Company is now in course of erection at Thornhill, and we are informed that a supply of electricity to power users within a reasonable distance of that station will be available on Dec. 1, 1904. The directors have appointed Mr. W. B. Woodhouse, A.M.I.M E., A.M.I.E.E., formerly engineer to the Newcastle Electric Supply Company, Limited, as resident engineer in charge of their business in Yorkshire.

Whitby.—Mr. L. H. King, in addition to his appointment as resident electrical engineer, has been appointed the consulting electrical engineer to the Council. Application is to be made for sanction to the raising of a further loan of £2,000 for the purpose of laying a feeder and for the further extension of cables. It has also been decided to have all the public lamps in the district electrically lighted. The Hotel Metrôpole is to be supplied with current by the Corporation. The Urban District Council have agreed to light the public footpath along the West Cliff top on the overhead wire system at a cost of £81.

Stock Exchange.—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: Eastern Telegraph Company, Limited, further issue of £44,435 3½ per cent. preference stock; Midland Electric Corporation for Power Distribution, Limited, £250,000 4½ per cent. first mortgage debentures, Nos. 1 to 1,750 of £100 each, and 1,751 to 1,900 of £500 each. The committee has further been asked to allow British Columbia Electric Railway Company, Limited, further issue of 1,500 5 per cent. cumulative perpetual preference shares of £10 each, fully paid, Nos. 51,001 to 52,500, to be quoted in the official list.

Greenock.—Mr. Jas. A. Robertson, burgh electrical engineer, in his last report, states that for the five weeks ended Nov. 7 82,887 units of electricity were generated for private and public supply, an increase of 23,482 when compared with the same period last year, and 77,857 units were generated for traction supply, an increase of 1,831. There are now 353 consumers, 54 more than at this period a year ago. It has been agreed to grant a supply of electricity to the Greenock Foundry Company, to be used when that company's own plant is not working, on condition that a consumption of energy equal to £11 per annum for a period of five years be guaranteed.

City of London.—At the last meeting of the Court of Common Council the Streets Committee brought up a report relative to a letter from the Board of Trade asking the views of the Corporation on an application by the undertakers under the St. Martin's Electric Lighting Order, 1899; the Strand District Electric Lighting Order, 1895; the Holborn and St. Giles's Electric Lighting Order (No. 2), 1898; and the City of London Electric Lighting Order, 1899, for consent to the transmission of energy up to 2,000 kw. in certain trunk mains in the City. It was decided that the Board of Trade should be informed that the Corporation had no observations to offer in the matter.

Steel Rolling.—The *South Wales Daily News* states that, in view of the growth of German and American competition, leading Midland steelmasters are considering the formation of a new steel bar combine, with works of its own in Staffordshire, equipped with latest electrical quick-rolling machinery. The Wolverhampton Corrugated Iron Company, which does a great foreign trade in galvanised sheets, has publicly declared its support, provided that British steel bars can be made in the Midlands as reasonably as Continental makers offer them. Several thousand tons of German steel bars continue to reach various Midland works weekly, where they are rolled into sheets and then galvanised.

Antony.—At the last meeting of the Parish Council the Lighting Committee reported that, having received Mr. Enright's report, they had distributed circulars to householders in Torpoint giving information with regard to electric lighting which had elicited responses undertaking to adopt the system up to the extent of 500 lights. This was independent of the public light. The time for taking the preliminary legal steps this year having passed, the committee recommended that the matter be deferred for further consideration until the formation of the Urban District Council, which body would have larger powers of dealing with the question of lighting than under existing circumstances. The report was adopted.

Exeter.—The Mayor, Mr. F. J. Widgery, on Monday switched on the current at the new electricity works of the Corporation at the Basin. The works will not be completed for some months, but in March the city will be supplied from the new station entirely, and all the work now done at the works at New North-road will be transferred to the Basin works. A portion of the generating plant is already in working order, and will supply current to the city and thereby relieve the heavy load on the station in New North-road. The new station has cost altogether £14,000, and comprises engine-rooms, boiler-room, coal stores, repairing shops, offices, economiser chamber, pump-rooms, etc. There are four sets, three of 550 h.p. and one of 150 h.p.

Bury.—With reference to the report in our last issue, we have received the following additional statistics for the year ended April 1, 1903. The figures in parentheses refer to the corresponding period in 1902: total capacity in kilowatts, 132 (132); maximum load, 108 (65); load factor, 16·4 (12·8); services connected, 139 (103); 8-c.p. lamps, equivalent, 8,197 (5,507); capital invested, £24,853 (£20,376); capital per unit sold, £·14 (£·27); average price obtained per unit, 3·17d. (3·92d.); public lighting price obtained per unit, 1·44d. (1·46d.); total cost, £2,574. 11s. 5d (£1,830. 14s. 4d.); coal, cost per unit sold, ·89d. (1·2d.); work cost per unit sold, 1·95d. (2 92d.); total cost per unit sold, 3 6d. (6d.); percentage of gross profit to capital, 3·81 per cent. (1·69 per cent.).

Ulster Electrical Power Distribution Co.—A company has been formed for the promotion of a scheme to obtain parliamentary powers for the supply of electrical energy upon a large scale over the province of Ulster, utilising water power where it is available, such as the Bann and the Erne rivers, and by the erection, where no water power is obtainable, of generating stations worked either with steam-engines or power-gas engines. This area contains numerous small industrial undertakings which require motive power only for two or three days a week, and to provide the same it is necessary to instal steam-boilers and engines which must necessarily lie idle a considerable time. To such industries a supply of electrical power ready for use when necessary would be productive of the greatest advantage and economy.

Edmonton.—The Works Committee of the Urban District Council reported at the last Council meeting that they had before them the reports of the electrical experts (Messrs. Hammond and Hawtayne) and also proposals from Messrs. Suter and Co., the Sir Hiram Maxim Electrical Engineering Company, the Industrial Engineering Company, and the North Metropolitan Electric Power Supply Company in respect to electric lighting, which were fully considered and discussed. The committee decided to adjourn the meeting for the engineer to obtain further information from the electrical experts, and also certain information from the Enfield District Council. The engineer was instructed to ascertain whether the Board of Trade would extend the time in which the Council are required to lay down suitable and sufficient distributing mains in Fore-street and the Green.

St. Annes.—The recent failure of the electric light has been investigated by Mr. J. H. Clothier, the town electrical engineer, who reports that the excessive rains flooded out one of the street boxes, and on another portion of mains the insulation had broken down and the cable burnt out. There are no traces left to point to the cause of the fault, but Mr. Clothier is inclined to think that the failure at this point was due to the heavy leakage current escaping from the lead covering to the earth through the wood bridge pieces, which do not appear to have been properly treated before laying, and have consequently become saturated with moisture. Mr. Clothier advocates a system whereby three districts should be formed, each to be fed by an independent feeder, so that inconvenience will be minimised should a similar event happen again. The Electric Lighting Sub-Committee have the engineer's recommendation under consideration.

Blackpool.—Mr. C. Furness in his last report states that there has been an increase during October in the works output of 4,828 units, made up as follows: lighting, 1903, 123,010 (1902, 133,631); Corporation trams, 79,074 (68,082); Lytham and St. Annes trams, 6,457—total, 206,541 (201,713). Mr. Furness points out that there is a decrease in the lighting output of 10,621 units, but the reduction in public street-lighting accounts for 4,212 units, and doubtless the autumn fêtes last year were responsible for more units being used than in the corresponding month this year. In answer to the advertisement for 450-kw. traction set, some 32 tenders were received, which were before the committee on Wednesday. The advertisement for offers for the small 50-kw. engines and alternators has only brought in two tenders, but several enquiries have been made, and Mr. Furness anticipates that at the next meeting there will probably be more offers for the plant.

Cheshire Power Scheme.—It will be remembered that last session a North-Western Electricity and Power Gas Bill passed through Parliament. Under this it was proposed to supply Cheshire and parts of Derbyshire, Staffordshire, Denbighshire, and Flint with electricity and power gas from suitable generating stations, and it is now proposed to seek power to carry out the suggestion of the Parliamentary Committee that a separate scheme should be provided for Cheshire. This will give a supply district of about 655,000 square miles, with a population of 827,000. Stations will be erected at Neston, Middlewich, Frodsham, Timperley, Bollington, and Dukinfield. The area to be served is to a large extent an industrial one, and it contains several districts which are essentially manufacturing. In the original scheme some of the stations in Cheshire would have served the contiguous parts of the surrounding counties, but as there will now be two systems it is proposed to enlarge the number of stations in Staffordshire, Derbyshire, and the two Welsh counties.

Burgess Hill Telephones.—On Saturday afternoon the union of Brighton and Burgess Hill in telephonic communication was officially inaugurated at the Burgess Hill Urban Council offices by means of an exchange of greetings between Mr. A. P. Scrase, J.P., chairman of the Urban Council, and Councillor Beryl, at Brighton Theatre Royal. The Mayor of Brighton, the chairman of the Telephone Committee, Mr. D. J. Barnes, engineer and manager, followed suit. The Corporation telephones have over 1,300 customers already, and have received 52 new orders within the last fortnight. They have a large number of orders at Burgess Hill, which they hope to execute within the next few days. The success of the Corporation in getting through to Burgess Hill has been entirely due to the support of the county and urban councils throughout the whole area. Burgess Hill would not have had telephones so cheaply but for the Corporation, and has been extremely lucky in getting such low terms, and they can communicate with National subscribers in any town except Brighton.

Macclesfield.—The following details of the electricity proposals appear in the *Macclesfield Courier*:—Messrs. Crompton: site, Mill-street and Derby-street; total plant capacity, 165 kw. or 2,760 16 c p., or equivalent; gas producers, Crossley's burning anthracite about 27s. per ton; guarantee, 1lb. of above coal per brake horse-power per hour; engines and dynamo, Crossley Crompton, belt driving from horizontal engine; mains, within compulsory area and few streets outside—cables laid and solid; approximate price, £16 000; buildings, no buildings included in above figure. The British Westinghouse Company: site, gasworks yard, fronting Commercial-road; total plant capacity, 600 kw. or 10,000 16-c.p. lamps, or equivalent; gas producers, one of several well-known local makes burning cheap slack about 7s. 6d. per ton; guarantee, 1½lb. of above coal per brake horse-power per hour; engines and dynamos, Westinghouse throughout, vertical engine direct coupled to generator; mains, within compulsory area, and outside where necessary—distributors solid, feeders in pipes; approximate price, £32,000: buildings, all buildings and foundations included in above figure.

Digitized by Google

Loughborough.—At a meeting of the Town Council, sitting as the General Purposes Committee, on Monday, the Gas Committee presented a report recommending the adoption of a scheme for the establishment of an electricity undertaking submitted by the engineer, Mr. Charles H. Gadsby. It is proposed to put down a plant of 500 kw. capacity only at first, comprising two sets of 250 kw. each, leaving the 100-kw. set out for the present, but so arranging the buildings as to allow of the 100-kw. set being added when required. The estimate is £28,408. The Council also reported that the plant on the Moor-lane baths site for providing a temporary supply of current to the works of Messrs. Herbert Morris and Bastert, Limited, was in working order by the time stipulated in the agreement with that firm, and is now running and supplying them with the current they require for lighting the whole of their works. The plant was at first worked by men provided by the Brush Company, but an engineer (Mr. G. H. Saunders) recommended by the Brush Company has now been engaged, and has taken charge of the works, and is, with a stoker who has been engaged to assist him, now running the plant, and the men supplied from the Brush Works have been withdrawn. The committee have decided to recommend that the charge to private consumers be—for lighting, 5d. per unit, and for power 2½d. per unit, with a provision for making special terms by agreement with large consumers.

London Gazette.—A receiving order has been made out in the estate of George Neale, electrician, 2, Fulham Palace-road, London, lately trading with another as South-Western Electrical Contracting and Maintenance Company. A general meeting of members of the Imperial Tramways (Old) Company will be held at Clare-street House, Bristol, on Dec. 19, at 12 noon, for the purpose of receiving the liquidator's statement and account. The partnership subsisting between Edward Thacker Mackrill, Edward Samuel Mackrill, and William Henry Mackrill, carrying on business at Aylesbury, Buckingham, as electrical engineers, under the style and firm of E. T. Mackrill and Sons, has been dissolved. All debts due and owing will be received and paid by Edward Samuel Mackrill and William Henry Mackrill, by whom the business will in future be carried on. A general meeting of the Electric Royalties Syndicate, Limited, will be held at 82, Victoria-street, Westminster, on Dec. 18, at 2 p.m., for the purpose of receiving the liquidator's accounts. The partnership subsisting between Albert Lester Taylor, Archie Kelly, and Walter James Hide, carrying on business as consulting electrical engineers at 36, Dale-street, Liverpool, under the style or firm of Lester Taylor, Kelly, and Hide, has been dissolved. All debts due and owing will be received and paid by Archie Kelly and Walter James Hide, who will carry on the business under the style of Kelly and Hide. The partnership subsisting between Haydn Thies Harrison, Frederick Startin Pilleau, and Philip Jefferson Brewer, carrying on business as electrical engineers at 11, Victoria-street, Westminster, S.W., under the style or firm of Haydn, Harrison, and Co., has been dissolved. All debts due to and owing will be received and paid by Haydn Thies Harrison and Philip Jefferson Brewer, who will continue the business.

Dundee.—At Monday's meeting of the Town Council the question of the condition of the electrical supply system was raised, and it was stated that they were about to take steps to borrow a sum of £74,000 to spend upon the electrical system, and they had it on the authority of the engineer that the greatest part of that expenditure was due to the old mains giving way, although these had been laid only 13 years. After discussion, it was decided to ask the engineer to report on any defects in the electrical system needing urgent attention. The *Dundee Advertiser* refers to the proposed formation of a company in the district for the provision of electric energy for the mills and factories of the city. This scheme apparently is still in the initial stage, but it is understood that a considerable amount of necessary data has already been obtained, and should the manufacturers show a disposition to discard their present power machinery, the promoters of the new scheme are confident of success. The intention is to construct a large generating station well to the north of the city, and supply electric energy as required to the public works. It will be necessary to obtain not only parliamentary sanction, but also an arrangement with the Town Council of Dundee for entering the Corporation territory. No approach has as yet been made to the Town Council. There is also some talk about using the water from Lintrathen for power purposes. In an interview, Mr. George Baxter, the water engineer, said, as reported in the same paper: "When I looked into the subject many years ago, I saw there was one scheme whereby Dundee might get about 5,000 h.p. from Lintrathen—namely, by increasing the storage capacity of the loch 12 times, putting a huge stone embankment across the bridge end of the bank, up the south side of the loch, bringing in the River Isla through the Horne of Needs, and laying steel flumes from the loch down to the bottom of the Den of Airlie, which is within a short distance. In that way you could utilise a fall of 250ft., and produce by that means 5,000 h.p. Or other resources could be built in the glens on the Isla, and on the Melgam above Lintrathen."

COLONIAL NOTES.

Bloemfontein.—The electric lighting scheme is now complete.

Durban.—An 800-h.p. engine has just been erected at the electric lighting station, and, with the 900 h.p. now on order, the Corporation will have 5,000 h.p. available for electric light and trams.

Mysore Goldfields (India).—A company has been registered under the title of the Kolar Mines Power Station, Limited, with a capital of £230,000, the object being to establish a central electric station in the district which contains the Mysore, the Champion Reef, Ooregum, and Nundydroog mines. We understand that Sir Chas. Tennant and Lord Ribblesdale are interested in the concern.

Madras.—*Indian Engineering* says: "We see that the Marshall-Crompton combine are exploiting Madras, and as this is almost an untilled field success should soon attend their energetic methods. There is a great need for a general supply undertaking in the southern capital, both for the purposes of lights and fans. Government and a few of the important leading firms have already put down some installations, but they have been beyond the reach of the general public, who would be quite as eager as the people of Calcutta to avail themselves of these necessities of modern life in India if they could be easily and cheaply procured."

Cape Town.—The ss. "Highland Corrie" was the first vessel to be discharged at Cape Town by the new installation of electric cranes for working cargoes. The ship's officers were well satisfied with the cranes, which worked without a hitch, and they think that the knowledge that Cape Town now possesses this improved means of discharge will attract shipping. The cranes are somewhat on the principle of ordinary cranes, and are unconnected with any system of cargo transporters. They are, therefore, not on the most approved principle, but with Delagoa Bay on the one hand and Cape Town on the other having adopted electrical appliances for working their cargoes, Durban should see the folly of clinging any longer to the ancient traditions of steam.—*South African Exports.*

Calcutta Jute Mills.—A large order has recently been awarded to the British Westinghouse Electric and Manufacturing Company, Limited, for two turbo generators and auxiliary plant, which will, it is believed, mark not only the first introduction of the large modern steam-turbine, but also one of the first extensive applications of electric power for factory driving in India. The plant in question will supply electric power to drive the large jute mill of Messrs. Birkmyre Bros. on the River Hugli, near Calcutta. The turbo-generators will each be of 1,300 kw. capacity, furnishing three-phase current at 440 volts and 25 periods. Each turbine will exhaust into a vertical surface condenser, having 4,800 square feet of cooling surface; and the exciter generators, of 20 kw. each, will be mounted direct on extensions of the turbine shaft. The turbines are to be of the multiple-expansion parallel flow type, running at 1,500 revolutions per minute. With steam at 1,175lb per square inch, 27½in. vacuum, and 200deg. F. superheat, a low steam consumption will be attained. The boilers will be eight in number, of the "Economic" type, supplied by Messrs. Davey, Paxman, and Co. The various departments of the mill will be driven throughout by Westinghouse polyphase induction motors, type C, of sizes varying up to 700 h.p. The 700-h.p. motors, three in all, will run at 290 revolutions per minute, and will be direct-coupled by solid flange couplings at each end of the spindle to 350ft. lengths of shafting. A large number of other motors will also be of the slow-speed type for direct coupling to the shafting without the intervention of belts or gearing. The contract includes, in addition to the above, the necessary switchboard and auxiliary apparatus, various transformers, and two jib cranes.

King William's Town (S.A.).—On Oct. 23 the electric lighting scheme of the King Electric Company, Limited, was successfully inaugurated by Mrs. George Whitaker, wife of the managing director of the company. The *Cape Mercury* says: "In the matter of the electric lighting of King William's Town the local Borough Council was first approached by Mr. E. G. Jones, the East London representative of Messrs. Reunert and Lenz, the contractors for the East London electric lighting and tramway scheme, but after considerable negotiations the above-mentioned firm declined the concession offered by the Borough Council, and for the time being the matter was dropped. The advantages which would accrue to the town if electric light was installed had made a great impression on some of the leading men of the town, and subsequently this important matter was taken in hand by Mr. George Whitaker, and very soon a limited liability company was formed on philanthropic lines, as follows: the shareholders not to receive more than 6 per cent., the overplus to be used for the improvement of the scheme for assisting the Town Council to buy the scheme out, thus enabling King William's Town to be lit by electricity some considerable time earlier than the finances of the Town Council would allow it to be done. The movement was very enthusiastically taken up, and in a very short time the whole of the capital and guarantees required were subscribed by local people. A board of directors was elected, Mr. E. G. Clifford Jones, M.I.E.E., was appointed consulting engineer, and the plans and specifications for the scheme were drawn up by him. The carrying out of the scheme was done on rather new principles. Plans and specifications were prepared for the individual apparatus and plant required, and tenders were called for both in South Africa and England. This enabled the company to deal directly with the manufacturers of the plant. The tenders were duly received, and the following firms were entrusted with the orders for the various items of plant: boilers, Messrs. Davey, Paxman, and Co., Limited, Colchester, England; engines, Messrs. Belliss and Morcom, Limited, Birmingham; dynamos and alternators, Electric Construction Company, Limited, Wolverhampton; condenser and feed pumps, Wheeler Condenser Company, Limited; steam-pipes, Babcock and Wilcox, Limited, Glasgow; underground high-tension cables, Glovers Limited, Manchester; poles, Messrs. Spends and Co., Limited, England; cross-arms and insulators, International Electric Engineering Company, Limited, London; bare copper wire, Messrs. Geipel and Lange, London; street brackets and stay-rods, Messrs. Reunert and Lenz, Johannesburg; and transformers, Ferranti Limited, London. The lighting is carried out on the single-phase high-tension alternating-current system. The current is generated at a potential of 2,100 volts, and is transformed down in nine transformer stations situated in different parts of the town to a potential of 220 volts for purposes of street-lighting and private supply. The power station is equipped with two Paxman Economic boilers, capable of generating 6,000lb. of steam per hour at a pressure of 140lb. to the square inch. These boilers are fed by two feed pumps, provided with a special arrangement for duplicate suction and feed mains and two independent water supplies. This arrangement was specially designed by the consulting engineer so as to give immunity from breakdown. The steam

Digitized by Google

is conveyed from the boilers through a specially arranged system of solid-drawn steel steam-pipes to the alternator and exciter engines, and the arrangements here are such as to give immunity from breakdown. The engine-room is equipped with two 50-kw. alternators and two direct-driving exciters. The exhaust steam from these is carried into a surface condenser situated in a pit in the engine room. The current from these generators is carried by underground cable situated in trenches to a specially-designed switchboard. At present only one alternator is required to meet the demand of street-lighting and private supply, but so many consumers have applied for private supply that arrangements are being made for the installation in the near future of another large steam alternator and another boiler. The engine-room is equipped with an overhead travelling crane capable of lifting any of the plant. The current is conveyed from the power station to the transformer houses by underground concentric, armoured, paper-insulated cables, and the secondary supply is conveyed from the transformer houses to the street lights and private consumers by bare copper overhead mains. The switchboard at the power station was specially designed by the consulting engineer to avoid accidents through the use of high-tension current, and specially designed cable terminal boxes and high-tension switch fuses have been installed in the transformer houses, so that it is utterly impossible for anyone entering a transformer house or the power station to receive a dangerous electric shock. The streets of the town are lit by 225 25-c.p. incandescent lamps, the switching of which is controlled from the power station. Up to date, applications have been received from about 100 private consumers for supply of electric current, and there is not the least doubt that in the near future this number will be very greatly augmented. The power station, as is generally known, is situated on the bank of the Buffalo River at Ninow's Dam, where there is an unfailing supply of water for condensing purposes. The building is of brick with concrete floor under iron roof, and was specially designed to give immunity from damage through fire. Messrs. Sharpe and Kenmuir were the building contractors. The cost of the scheme to date is £18,000. Current for street-lighting will be supplied at 7d. per unit, and to private consumers at 1s. 3d. per unit. It is the intention of the directorate to reduce these rates as soon as the scheme is on a favourable footing. Great attention has been given to the installation of an economical system, and the whole of the works will be run by a staff consisting of the resident engineer (Mr. G. E. Saunders, formerly of the Hampstead Corporation electricity works), five white men, and eight natives. Mr. A. Scott has had charge of the power station since the work commenced, and will continue in that position. The whole scheme has been designed and carried out under the personal superintendence of Mr. E. G. Clifford Jones, M.I.M.E., late city electrical engineer, Cape Town; resident engineer, Cape Town; tramways and town electric engineer, East London."

PROVISIONAL PATENTS, 1903.

Nov. 9.

24244. An improved method of supporting trolley wires on electric tramways, railways, canals, and the electric operation of road vehicles. Percy Sewell Sheardown, Danum, Pembroke-park, Clyde-road, Dublin.

24248. Improvements in and connected with collectors of electricity for railways and tramways. Robert Cumming, 249, West George-street, Glasgow.

24282. Improvements in electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24283. An improved electric switch with indicator. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24284. Improvements in third-rail insulators for electric railways. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24285. Improvements in electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24285. Improvements in a double-throw electric switch with indicator. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24302. Improvements in magneto-electric induction apparatus. Arthur George Bloxam, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Alfred Schoeller, Germany.) (Complete specification.)

24305. Improvements relating to the electrical deposition of smoke, fume, mist, fog, and the like. Oliver Joseph Lodge, Kt., 18, Southampton-buildings, Chancery-lane, London.

24310. Improvements in magnetic inductors. The Aktien Gesellschaft "Magneta" (Electrische Uhren ohne Batterie und ohne Contacte), 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Jan. 20, 1903, being date of application in Switzerland.) (Complete specification.)

Nov. 10.

24333. Sparking plug, or device for electrical ignition of oil-engines, gas-engines, and the like. Malcolm Cooper, Dell's Farm, Beresford-road, Highbury, London.

24366. Improvements in magnetic compasses. George Charles Lilley, Billiter House, Billiter-street, London.

24396. Improvements in and relating to galvanic batteries. Elizabeth Marie Risac, 323, High Holborn, London. (Complete specification.)

24413. Improvements relating to electric current meters. Edward Jesse Piper, 24, Southampton-buildings, Chancery-lane, London.

Nov. 11.

24444. An improvement in ships' telegraphs. George Green and Francis E. Prior, 298, Old Chester-road, Rock Ferry.

24445. Improvements in electricity meters. George Hookham, 18, Southampton-buildings, Chancery-lane, London.

24449. An improved sparking plug or electrical ignition device. Graham Francis Henry Satow, 10, St. George's-crescent, Liverpool.

24465. Positive electrode for a galvanic battery. Gustav Heinrich Carl Kolosche, 81, High Holborn, London.

24469. A new or improved suspending chain for electric lamps and the like. James Hinks and Son, Limited, and Arthur Henry Wright, 7, Staple-inn, London.

24472. Improvements in electric furnaces. Ernst Ruhstrat and Walther Eugen Grimmer, 10, Reinhauser-chausse, Gottingen, Germany. (Complete specification.)

24474. Improved apparatus for automatically controlling the speed of Wheatstone telegraphic transmitters and the like. John Gell, 21, Finsbury-pavement, London.

24483. An improved electrical switch. Edwin Liddle and Guy Emanuel Druiff, 47, Hatton-garden, London.

24500. Transmitting alternating current through a vapour. Ezechiel Weintraub, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, March 23, 1903, being date of application in United States.) (Complete specification.)

24501. Rectifying alternating current. Ezechiel Weintraub, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, March 23, 1903, being date of application in United States.) (Complete specification.)

24502. Improvements in transmitting alternating current through a vaporous conducting medium. Ezechiel Weintraub, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, May 9, 1903, being date of application in United States. (Complete specification).

24515. Improvements in and relating to automatic transmitting apparatus for telegraphic and analogous purposes. James Tarbotton Armstrong and Axel Orling, 323, High Holborn, London.

24516. Improvements in and relating to receiving or detecting and recording apparatus for telegraphic and other electrical purposes. James Tarbotton Armstrong and Axel Orling, 323, High Holborn, London.

Nov. 12.

24581. An improved portable electric fan. Max Margowski, 72, Cannon-street, London.

24621. An improved automatic guide for engaging trolley heads of electric cars with overhead wires. John Edwin Hopthrow, sen., and John Edwin Hopthrow, jun., 5, Hatton-garden, London.

24623. Improvements in controlling an electric generator dynamo, or booster and battery for constant or variable pressure. Arthur George Bird, 18, Buckingham-street, Strand, London.

24626. Improvements in or relating to plates for secondary batteries. William Phillips Thompson, 322, High Holborn, London. (Pfluger Accumulatoren-Werke Actiengesellschaft, Germany.)

24630. Improvements in current-collecting devices for electric railway vehicles. Joshua Shaw, 6, Lord-street, Liverpool.

Nov. 13.

24680. An electrograph or apparatus for the electrical transmission, reception, recording, and reproduction of sound. Ernest George Craven, Devereux House, Campbell-road, Twickenham, London.

24693 Improvements in telephone apparatus Jules Cerpaux, 65, Chancery-lane, London.

24695. Improvements in or connected with means for electrically igniting miners' safety lamps. John Charles Best, 33, Chancery-lane, London.

24701. Improvements in and relating to electric motion in conjunction with the creation and multiplication of electricity applicable to machinery of all kinds requiring power. Thomas James Howell, 93, King's Cross-road, London. (Complete specification.)

24706. Improvements in rails for electric trams, railways, and for other similar suitable purposes. Thomas Lister Patchett and William Buck, 8, Quality-court, Chancery-lane, London.

24730. Improvements in dynamo-electric machines. John Herbert St. Hill Mawdsley, Norfolk House, Norfolk-street, Strand, London.

Nov. 14.

24755. Improvements in or relating to electrical fuse holders, fuse boxes, and the like. Francis Gibson Baily, 11 Ramsay-garden, Edinburgh.

Digitized by Google

24770. Improvements in and relating to devices for making electrical contact in cables, armatures, and other electrical appliances. Henry Morrison Bremner, 96, Buchanan-street, Glasgow.

24791. Improved means for synchronising dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24792. Improvements in electric cut-outs. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24793. Improvements in fluid pressure regulators. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24794. Improvements in arc-extinguishing devices. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24795. Improvements in electric cut-outs or fuses. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24796. Improvements in emergency brakes for railway and tramway vehicles or trains. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24797. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24798. Improvements in electrically-driven vehicles. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24799. Improvements in electric motor systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24800. Improvements in braking systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24806. Process for the electrolytic manufacture of peroxides of magnesium and zinc. Friedrich Hinz, 37, Essex-street, Strand, London.

24833. Spark intensifier for electric igniters for explosion motors. Alfred Wydts and Joseph Klopfenstein, 53, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 3, 1903.

1902.

19647. Electric elevators or lifts. Bremner.

21969. Electric meter. Halsey. (Date applied for under International Convention, March 13, 1902.)

22024. Lifeguards or fenders for electric cars and other road vehicles. Munro, Brecknell, and Rogers.

22135. Electrolytic decomposition of alkaline chlorides. Gilmour.

24325. Apparatus for use in testing electric lamps. Wilson and Hardingham.

24744. Lightning guards, specially applicable for submarine telegraphy. Lodge and Saunders.

24772. Electrical transformers. Berry and British Electric Transformer Manufacturing Company, Limited.

25085. Switches for use in electric lighting. Quaney and Kirwan.

25216. Electrical cut-outs and regulators and their application. Leitner and Lucas.

26039. Electric train-control systems. Carolan. (General Electric Company.)

26647. Electric recording instruments. Carolan. (General Electric Company.)

26818. Incandescent electric lamps and collars for the same. Cleminson.

26906. Junction frog plates for use on the overhead system of electric tramways. Foster.

26917. Switching mechanism applicable for intercommunication telephone systems. Byng and Anders.

27133. Enclosed electric arc lamps. Reclus, Petitdidier, Schmitt.

27272. Method of selective electric signalling. Lake. (Stone.)

27373. Galvanic cell. Pearson and Fiedler.

27374. Electrode for galvanic cells, and a method or process for producing same. Pearson and Fiedler.

27476. Electric railway or tramway traction on a surface-contact or like systems. Boult and Boult.

25574. Reversible boosters. Peebles and Pickstone.

27755. Electric furnaces or muffles. Carolan. (General Electric Company.)

27758. Machines for cutting micanite and the like. Carolan. (General Electric Company.)

27765. Electric phase-indicating instruments. Carolan. (General Electric Company.)

27769. Electric rheostat switches. Carolan. (General Electric Company.)

27771. Electromagnetic locks for automatic electric circuit breakers. Carolan. (General Electric Company.)

28510. Trolley poles of electric tramcars and the like. Hommel and Hommel.

28643. Supporting devices for trolleys for overhead electric traction. Kennington and Fawcett.

1903.

10. Automatic suspension and contact appliance for electric arc lamps and other apparatus requiring to be raised or lowered. Stevenson.

273. Manufacture of electrodes for secondary batteries. Müller.

517. Miners' lamps that are ignited by means of electricity. Naylor.

518. Back gearing appliances for electric motors and dynamos and for steam and water-driven turbines. Davidson.

778. Device for indicating the condition of the electric circuit controlling the air brake valves on a train. Siemens Bros. and Co., Limited. (Siemens und Halske Actiengesellschaft.)

1088. Manufacture of positive electrodes for secondary batteries. Roderbourg.

2874. Switches for controlling an electric circuit from several points. Terry.

19524. Manhole terminals for electrical conduit sections. Gest.

20061. Receivers for wireless communication. Morin.

NOTES.

Engineering Standards Committee.—This committee have appointed Messrs. Crosby Lockwood and Son, of 7, Stationers' Hall-court, E.C., as their official publishers. All the reports and specifications published by the committee may be had either from that firm or direct from the offices of the committee, 28, Victoria-street, Westminster.

Royal Meteorological Society. — The opening meeting of this society for the present session was held on the 18th inst., at which Dr. H. R. Mill and Mr. R. G. K. Lempfert contributed an elaborate and interesting paper on "The Great Dustfall of February, 1903, and its Origin." The authors came to the conclusion that the dust originated on the West Coast of Africa, taking two days to reach this country.

Trials of Electric Automobiles.—In May next year it is proposed by the Automobile Club to hold a series of trials of electrical vehicles. Draft conditions have been prepared and the makers and agents of electrical vehicles in this country have been asked whether they would be prepared to make a definite entry now, as the club have decided that in the event of fewer than 10 entries being received from this country no trials will be held.

American Institute.—The October number of the *Transactions* of the American Institute of Electrical Engineers has just reached us. It continues the reprint of the papers and the discussions thereon at the Niagara Falls convention for the two last days of the meeting—viz., July 2 and July 3—and also reports the proceedings at the September meeting in New York, when President Arnold delivered his inaugural address. Two papers were read at this meeting—*i.e.*, "An Efficient High-Pressure Water-Power Plant," by Mr. Geo. J. Henry, jun., and Mr. Jos. N. Le Comte; and "Electric Motors for Centrifugal Pumps and Fans," by Mr. A. J. Bowie, jun.

Electricity Supply Areas in London.—Our readers must by now be familiar with that hardy perennial, the Bill promoted by the Board of Trade for altering and readjusting the electricity supply areas in London. Twice has it been presented to Parliament in two consecutive sessions and twice withdrawn, for reasons unexplained. The Board of Trade will again bring the Bill forward in the new session, but as to its ultimate fate we decline to anticipate. The matter with which the measure deals may not be of first importance in these days of educational and fiscal reform, but it strikes us that it is quite time the areas of electricity supply in the Metropolis as affected by the passing of the London Government Act in 1899 should be definitely defined.

Soldering of Aluminium.—A method of perfectly soldering and brazing aluminium is reported to have been achieved by a young French savant after four years' experiments. He is also stated to have discovered a process for hardening the metal, and greatly increasing its powers of resistance without adding to its weight. Should the invention prove to be successful in practice, it will undoubtedly lead to the more extended use of aluminium for electrical transmission. Perhaps the greatest obstacle in the way of the successful employment of aluminium for electrical conductors has been the soldering difficulty. Although many methods have been devised for improving these conditions, no one, so far as we know, has been completely satisfactory.

British Electrical Instruments at St. Louis.—There is every reason to believe that the British electrical industry in its various spheres will be well represented at the World's Fair to be held at St. Louis next year. In this connection the value of the Royal Commission appointed to assist in arranging for English exhibits is fittingly illustrated. Under the guidance of this Commission the electrical instrument makers of Great Britain are arranging a collective exhibit of great variety, which, in its complete form, will be forwarded to St. Louis in one consignment, thus enormously reducing the expenses of the individual exhibitors. We may mention that among the exhibits will be a platinum resistance thermometer capable of measuring temperatures from that of liquid air up to 1,400deg. C.

Cable Telegraph Record.—The cricket season in Australia has afforded an excellent opportunity for testing the possibilities of the cable lines between the Commonwealth and this country on the point of speed of transmission. On Saturday both the Eastern Telegraph Company and the new Pacific line made a determined bid for the supremacy, and the result was that a record was established in cable telegraphy from Australia. Identical messages were handed in at the two offices in Sydney at the same hour, giving the close-of-play score in the cricket match then in progress. The Eastern Telegraph Company delivered the message in London 13 minutes later, while the message sent by the Pacific route came through hardly a minute behind the other—the former making an absolute record for a public telegram from Australia to this country.

Post Office Telephone Rights.—We congratulate the Post Office on its victory in the case heard at Kingston-upon-Thames County Court on Friday, the point at issue being whether it was entitled to erect wooden poles at Wimbledon in connection with the extension of the Post Office telephone system in that district. The local authority objected to the erection of wooden poles on the ground that the æsthetic aspect of the roads would be spoiled in consequence, and attempted to force the Post Office to put the wires underground in some cases and to use ornamental iron poles in others, by withholding their consent to the work being carried out. This would mean a large increased expenditure, and the Post Office accordingly took county court proceedings to test the point. The judge held that painted wooden poles would not much interfere with the æsthetic character of the neighbourhood, and gave his decision in favour of the Post Office.

Telegraph Facilities in Rural Districts.—A very useful extension of the present system of delivery by hand, or by "express" or ordinary post, of telephonic messages received at central postal offices is about to be made in Lancashire. In certain part of that county the old A B C instruments are still in use, and instead of replacing them with the latest form of telegraph instrument, a substitute will be found in the telephone. It is thought that this instrument will prove more efficacious than the telegraph for the transmission of outlying messages, because of the scarcity of trained operators in the rural districts. Under this system the message will simply be telephoned through to the nearest telegraph office, and redispatched by hand or by post, as required. We understand that the new arrangement will presently be extended to every post office in the kingdom which is also a telegraph office, and telephonic and telegraphic communication with outlying districts should thus be greatly facilitated.

Embankment Tramways.—Among the important legislative proposals which the London County Council will bring before Parliament next session is one for a series of new tramways, including the oft-rejected line along the Victoria-embankment. Since its first introduction in the House of Commons this scheme has met with strong

Digitized by Google

opposition, for reasons more æsthetic than practical, the opinion being that an electric tramway along the embankment would spoil the present picturesque aspect of that thoroughfare. However, the opponents of the schome only succeeded in obtaining its defeat last session by a single vote. Now it is hoped that the opening up of the new highway between Holborn and the Strand will help to influence Parliament in favour of the proposed tramway, which, as in its original form, aims at providing the connecting link between the Council's system south of the water and the North London lines by means of the shallow underground tramways now under construction from Theobalds-road, Holborn, beneath the new Kingsway, to the Strand.

Municipal Telephony.—A new objection has been raised by Mr. W. Gaine, of the Telephone Company, against the methods of municipal telephony. He takes the view that the practice adopted by most municipal corporations in this country owning a telephone exchange of making no charge to their subscribers until they can guarantee them connection with a certain number of others, is a breach of the provisions of the licenses granted by the Postmaster-General. The case in point is the Brighton municipal undertaking, and Mr. Gaine declares the view of his company to be that the first subscribers to the system are obtaining an undue preference as against subsequent subscribers. This, however, is not the case, for the Corporation could not fairly ask their subscribers to pay for a service which is not in full working order. There is no question of "favour" or "preference" here as guarded against in the Corporation license; it is the usual practice adopted in the early stages of a municipal undertaking, which is dependent for its success on the amount of support it can get at the beginning.

Junior Institution of Engineers.—At the meeting of this institution held at the Westminster Palace Hotel on 20th inst., a paper on "Fires on Shipboard: Their Causes and the Methods for Prevention and Extinction," was read by Mr. George Canning. The author dealt with the losses sustained through fire casualties amongst shipping, and urged the adoption of gas systems, which he maintained were the only feasible methods extant, not only for the prevention, but also for the extinction of fires on shipboard. On the following day, by invitation of the Clayton Company, the institution witnessed a demonstration of fire-extinguishing at Orchard-place, Blackwall. The apparatus shown in operation consisted of a sulphur chamber or generator, in combination with a blower and engine, and a cooler. Ordinary rolled sulphur is placed in the generator and set alight by means of a piece of waste. Two pipes are fitted to the generator, one for delivering the gas to where the combustion is taking place, and the other as a return or suction pipe. Air taken from the compartment to be treated enters the generator, and the oxygen combining with the sulphur vapours produces sulphur polyoxide gas. The demonstration was attended by successful results.

New Books.—"Report on the Influence of Gauge Length and Section of Test Bar on the Percentage of Elongation," by Prof. W. C. Unwin (Messrs. Crosby Lockwood and Son. 2s. 6d.). This report deals with the variation of percentage of elongation with different gauge lengths and sections of test bar, and is issued in connection with the excellent work which is being carried on by the Engineering Standards Committee. It is based almost entirely on tests of steel-plate test bars supplied by the Dalzell Steelworks, Motherwell, and the Parkgate Steelworks. These tests cover a wide range of conditions, and no such complete information as to variation of elongation with the form of test bar has been previously available. As the results are, it is believed, valuable whatever decision may be arrived at as to standard forms of test bars, they have been very fully and critically discussed by the author. "The Practical Electrician's Pocket-Book and Diary, 1904" (Messrs. S. Rentell and Co., Limited, Strand, W.C. 1s.). This admirable little book has now reached its sixth year, and is no exception to the previous issues, in that it succeeds in keeping pace with the most recent developments of electrical practice Many alterations and additions have been made to the matter, so that the electrician and fitter will find it quite trustworthy. With the growth of the industry the tabulated list of central stations with particulars of current and rates has now grown to considerable dimensions, and this represents not the least interesting section of the book.

The Speed of Tramcars.—It was hardly to be expected that the energetic managing director of the London United Tramways, Mr. J. Clifton Robinson, would be content to take an inactive part in the campaign which Mr. Moffat Ford has commenced against the speed of electric tramcars as reflected in the recent proceedings at the West London Police Court. As we showed in our last issue, Mr. Ford has attempted to establish that he is working for the public good, but at the same time he urges that even more stringent regulations should be imposed on electric tramcars than on motorcars, his argument being that the motorcar weighs considerably less, has at least two sets of efficient brakes, and can steer clear of danger, while the heavier tramcar can avoid danger only by use of its brakes. Mr. Clifton Robinson, in a letter to the *Times*, completely disposes of these points when he says that, to the average man in the street, an electric tramcar is a known quantity, while the motorcar is not. Hence the latter constitutes a greater source of danger than the tramcar pursuing its rigid and defined course. The fundamental differences between motorcars and tramcars offer no real basis of comparison, and if Mr. Ford thinks he is going to achieve his avowed object by prosecuting individual tram-drivers, we fancy he is mistaken. As Mr. Clifton Robinson truly says, the prosecution of the driver of a private motorcar for excessive speed does not justify retaliation on the part of that individual by seeking "to hamper the operations of a public tramway system, to the inconvenience of the 50 millions of passengers who travel yearly on its electric cars."

The Metric System.—It may be within the knowledge of some of our readers that last August a congress of chambers of commerce of Great Britain and the Empire was held at Montreal, at which a decision was come to in favour of the adoption of the metric system of weights and measures. Details of this decision, however, are only now available. It seems that at the meeting there were present delegates from 75 British chambers of commerce, and from the chambers of the principal cities of India, Ceylon, Egypt, South and Central Africa, Canada, the West Indies, Australasia, Hong Kong, and Malta. In the discussion of the question it was urged that the matter should be so forced upon the Government that it would be bound to take action. The resolution, which was adopted with but few dissentients, reads as follows: "That this congress, having had under its consideration the following resolution, adopted at the conference held in London during the months of June, July, and August, 1902, between his Majesty's Principal Secretary of State for the Colonies and the Prime Ministers of the self-governing colonies of the British Empire—namely, 'That it is advisable to adopt the metric system of weights and measures for use within the Empire, and the Prime Ministers urge the Governments

Digitized by Google

represented at this conference to give consideration to the question of its early adoption'—hereby expresses its hearty concurrence therewith, and urges upon the Government of the United Kingdom the necessity for legislative measures being taken in the interests of British trade and commerce to make the use of metric weights and measures compulsory."

Electricity in Ladysmith.—So enthusiastically is the electric light being taken up in the South African town of Ladysmith, of famous memory, that we learn further extensions of plant are already decided upon. The present installation gives supply on the three-wire, direct-current system, with 400 volts between the outer wires, the middle wire being earthed. All the supply mains are carried overhead on iron poles, the two outer wires being supported on porcelain insulators fixed on wooden cross arms, while the middle wire is bound to a special clamp on the pole itself, and is thus earthed at every pole on the line. This is one of the main features of the distributing system, the possibility of danger being reduced to a minimum. In the generating station there are two sets of engines and dynamos, each consisting of a compound two-crank Willans and Robinson engine, to which are coupled two continuous-current compound-wound generators. Each set has a capacity of about 65 kw. as a maximum, and the two generators of each set are arranged to be connected on opposite sides of the three-wire system, so that each engine with its two generators supplies current to both sides of the mains to the extent of its capacity. Steam is supplied by three Robey boilers. The main switchboard consists of two generator panels and six feeder panels, with room for additions. The panels are of polished marble, and, in addition to the measuring and regulating apparatus, they only carry switches and fuses connected to the outer 'bus bars, the middle 'bus bar being earthed and having all connections joined to it. A subsidiary switchboard controls the street-lighting circuits. We understand that the performance of the plant so far gives every reason for satisfaction, and it is anticipated that the undertaking will be on a paying basis in the second or third year of its existence.

Possibilities of Electric Traction.—Mr. G. H. Sheffield, the new president of the Newcastle Association of Students of the Institution of Civil Engineers, made some noteworthy remarks on the possibilities of electric traction in the course of his address at the opening meeting of the association a few days ago. If the railway companies, he said, were to retain their suburban traffic, they had no alternative but to electrify their local lines, and he mentioned 50 millions sterling as a "conservative estimate" of the cost of doing this. The adoption of electric traction on such lines would lead to greater progress in 10 years than had been seen in 30 years with steam traction. As regards the main lines, there was a possibility of matters being precipitated by the establishment of independent express lines in competition with the existing railways, but at the present the problem was surrounded by difficulties. Discussing the better system of working to adopt—the third rail or the overhead—Mr. Sheffield threw out the hint that as the latter was the cheaper it should be tried for suburban traffic, using the bow trolley as in Germany. He then referred to the advantage of electric tramways or light railways for the carriage of merchandise, remarking that if the railways took a common-sense business view of the matter they would accept the inevitable, and encourage goods traffic on electric tramways by making connections with their goods yards and warehouses. In this way the tramways would act as valuable feeders to the railways, which would be able to reduce their costly cartage departments. He saw no reason either why specially-constructed tramway wagons should not be allowed to run over the railway systems, thus enabling them to work colliery sidings and factories. In conclusion, he advocated the standardisation of all tramway rolling-stock to permit of free interchange of traffic on adjacent systems.

Electrolysis of Fused Lead Chloride.—The *Journal* of the Chemical Society for November contains an abstract of a paper by Mr. A. Appelberg describing some experiments he has made regarding the electrolysis of fused lead chloride with reference to its connection with current density and current yield. The author has determined the current yield and studied the phenomena which occur at the cathode and at the anode in the electrolysis of fused lead chloride. The arrangement was similar to that used by Helfenstein in previous work, and the fused lead chloride was contained in a V-tube. The results (exhibited in tables and graphically) which are obtained with varying current density show that as the density decreases the yield of lead diminishes regularly. If the current yield curve be extrapolated, it meets the current strength axis at about 0·05 ampere; therefore, if the current strength is reduced below this, no lead is separated. The minimum current intensity corresponding with this point is about 0·6 volt, but these values are not absolute, since they vary with the conditions of the experiment—such as temperature and distance between the electrodes. With high-current densities the polarisation is almost constant at 1·25 volts, and is independent of the density. The chlorine yield was determined by Auerbach's method, using varying current density. With high densities the yield agrees with the lead yield, but with low densities the agreement is not good, and this is to be attributed to variation of the experimental conditions. The electrolysis takes place in a cylindrical vessel standing either vertically or obliquely, just as in the V-tube; in all cases the current yield is independent of the duration of the electrolysis. When a cylindrical cell was used, a cloud of lead was always produced in the lead chloride; in order to avoid this a current of chlorine was passed throug the fused mass, but this was not successful and it lowered the current yield.

Railway Electrification.—"A Correspondent" contributes a three-column article to the *Times* of Tuesday under this title, but he does not enter into any especially controversial points. For instance, experts are agreed that a certain part of the traffic abstracted from railways can be better handled by trams and tubes than by steam trains, but that if the railway companies were to electrify their local lines they would succeed up to a certain point in stemming the present severe competition of the newer forms of locomotion. The real solution of the problem is to be found in a more rapid acceleration of the trains, and this can only be effected by adopting electric traction. The writer thinks that, under certain conditions in this country, the reduction in the cost of working by electricity would be sufficient to meet the interest upon the capital outlay. This cost of working, however, is largely dependent upon the price at which electric current can be obtained, and the writer regards the ideal arrangement as being that existing in the case of the North-Eastern Railway, where the company is obtaining its supply from a power company which, owing to the variety and extent of its load, can produce and sell at a far lower figure than any independent station. It is to be hoped that the railway companies in the neighbourhood of London, when the time should arrive, will co-operate as far as possible in obtaining their supply of electricity. Now that many of the large electrical companies are moving their stations into the outskirts of London in order that they may generate current

Digitized by Google

under more favourable and economical conditions than hitherto, it should be possible for some of the suburban railways to arrange with them for the supply of current at a reasonable figure. The writer concludes that a carefully designed scheme of electrification could be carried out at a much lower cost than is generally supposed to be the case.

Telephones in Paris.—A report has been issued by Mr. Marcel Lembat, a member of the Chamber of Deputies, on the postal telegraph and telephone services in France during 1903, a very interesting portion of which deals with what is called the telephone crisis in Paris. Mr. Lembat notes that the subscription rate in that city is £16 per annum, and although the administration promised to reduce this rate to £12, nothing has been done in the matter. For the present rate an unlimited number of conversations is allowed within the Paris area proper, which embraces 48 exchanges. There were in the city on Oct. 31, 1902, total connections to the number of 40,555, or only 1·49 connections for every 100 inhabitants, this being much lower than the average for other European cities or in America. The apparatus, with the exception of the batteries, has to be supplied by the subscribers at their own cost, but the maintenance is at the cost of the State. The patronage of the system is not extensive, as it appears that the daily use of the instrument does not reach above five conversations on the part of 53 per cent. of the subscribers, while less than 9 per cent. use the telephone more than 15 times a day. Under these circumstances, Mr. Lembat advocates the message-rate system, which is working well in many countries at the present time, and has resulted in a remarkable increase of subscribers. He insists that a reform of this kind ought to be made, although considerable change in mechanism and apparatus would be necessary. The telephone service provided in Paris at the present time is described as inferior, and great difficulty is often experienced in getting com munication. Mr. Lembat closes with the satirical enquiry, What would happen if a private company dared to do that which the State is at present doing, and strongly recommends the Government to lower the flat rate and institute the message-rate system.

Industrial Decentralisation.—At the Surveyors' Institution on Monday night a paper was read by Mr. Herbert T. Scoble on "Industrial Decentralisation an Important Factor in the Solution of the Housing Problem." The author state that a comparison of the advantages and disadvantages of town and country with regard to factories and labour showed a substantial balance in favour of the latter, though exceptional cases would occur from time to time, and must be taken into account. Descriptions given of two recently erected factories, one rural and one suburban, lent weight to the author's contention that decentralisation pays, and it was stated that most substantial economies are made in the handling of goods, in rent, rates, insurance against fire, etc. The model villages of Port Sunlight and Bournville were dealt with, and the design and accommodation of the cottages received special attention. The effects of decentralisation were considered as regards manufacturers, workers, and the community; and a case was quoted where, by removal to the country, manufacturers of machinery were enabled to reduce the price of their goods by no less than 20 per cent. Mr. Scoble's view is that by migration to rural or semi-rural districts the manufacturer will be in a position to produce more cheaply; that if he studies the interests of his workpeople, comfortable houses will be erected for them; and that, by virtue of the lessened cost of manufacture, more successful competition in the home, colonial, and foreign markets may be expected. The establishment of factories in the country and the housing of labour in the immediate vicinity will do more to solve one of the most pressing problems that have to be dealt with—viz., the housing of the working classes—than the erection by municipal or philanthropic effort of tenement buildings in towns near our industrial centres, or the provision of transit facilities which must inevitably lead to greater congestion.

Indian Telegraphs.—The chief point that strikes one in looking through the report of the Indian Telegraph Department for the year 1902-3, which has just reached this country, is the proportionately small loss incurred through the reduction in the rates of cable messages between India and Europe from 4s. to 2s. 6d. a word. This favourable result can only be traced to the increased business which the lowering of the rates brought in its wake. Thus, the foreign private message revenue only fell off by 3½ lakhs, and this was due not so much to the reduction in the rates as to the diversion of the Australian traffic with Europe, formerly transmitted *viâ* India, to the direct cable route *viâ* South Africa. The total receipts for the year amounted to 112½ lakhs of rupees, showing a slight advance on those of the previous year, and the net profit gave a return of 4·15 per cent. on the aggregate capital expenditure of over 795 lakhs. With regard to the present position of the department, there were at the end of the year under review 5,652 telegraph offices, 56,830 miles of lines, and over 200,000 miles of wire. The report states that the Wheatstone automatic apparatus has proved invaluable in disposing of the traffic in times of pressure and prolonged interruptions of communication, and was of great assistance in connection with the work entailed on the department by the Delhi Durbar. Coincident with the issue of this report, the Indian Government announces a revised inland tariff, reducing the charges for all three classes of messages known as urgent, ordinary, and deferred, and also for Press messages. For the first class of messages the new rate is two rupees for 16 words, and is double that for ordinary telegrams. The minimum charge for deferred messages has been correspondingly decreased from eight annas to four annas. Under the system prevailing in India the address of six words is sent free of charge, and four words of message can be sent for four annas, each additional word being charged one anna.

Dublin Local Section.—The address delivered at the inaugural meeting of the Dublin Local Section of the Institution of Electrical Engineers on the 12th inst. by its chairman, Prof. W. E. Thrift, may be described as a general review of present-day progress in matters electrical, which embraced many of the latest and more important inventions of electrical science. From the Nernst lamp—for which the professor predicted a great future—to the steam-turbine, the gas-engine, the three-phase induction motor, the single-phase motor, and the Cooper-Hewitt mercury vapour lamp, the author passed in quick succession, describing the principal features of each and offering some comments. Particular reference was made to the Curtis steam-turbine, and in passing it was noted that the claim is made for it that the efficiency at light loads is nearly as high as that at full load. The gas-engine he regarded as likely to prove a formidable competitor of the steam-engine in driving large-type generators, whether for power or lighting purposes. On the other hand, attempts are being made to increase the efficiency of the steam-engine by combining with it a vapour-pressure engine, but it yet remains to be seen whether in practice the increased economy in working makes up for the increased initial expenditure. On the subject of electric traction,

Digitized by Google

it was noted that the present year has witnessed the first conversion in the United Kingdom of a steam railway into an electric railway, the reference, of course, being to the Mersey Railway. The author passed on to refer to local affairs, particularly to the completion of the new city lighting scheme, by which Dublin is provided with three-phase current generated at the Pigeon House. A long treatise on polyphase motors followed, special reference being made to the successful work of Mr. Heyland in this field, and of M. Latour. The next section of the address was devoted to the recent discoveries of radio-active bodies, which have opened up a new sphere of analysis and investigation, and the author expressed the belief that in radium there may be found the long-sought-for cure for cancer and consumption. The electron theory is little more than in the initial stage of its mathematical development, but it presents problems to the mathematician to solve of almost infinite variety and complexity, whether with regard to its own nature and properties, the explanation of gravitation and the proportionality of mass and weight, or in reference to the part which it plays in the structure of the atom.

Electricity in Railway Workshops.—The Government of Queensland, Australia, has recently completely reconstructed its large railway workshops at Ipswich, and as a natural consequence, perhaps, the electric drive has been adopted for all the large machine tools. The decision to equip the new works for electrical working was only come to after exhaustive enquiry, which showed that the electric drive was most economical and the most suitable for the conditions to be encountered. The works comprise 14 different shops, covering an area of five acres; and the distribution of the electric power is carried out by underground conductors. The power plant which has been laid down consists of three generating sets, each set being made up of a 200-kw. Westinghouse two-phase generator, directly connected to a Westinghouse compound engine, and controlled from a white marble switchboard. The generators are of the rotating armature type, delivering two-phase alternating current at 60 cycles and 220 volts. These generators carry full load continuous at 90 per cent. power factor, with a rise in temperature in any part not exceeding 40deg. C.; with a 25 per cent. overload the rise under the same conditions does not exceed 50deg. C. The machines have an efficiency of 93 per cent. under full non-inductive load. The exciting plant consists of a 17½-kw. Westinghouse engine type generator, directly connected to a Westinghouse 8½ by 8 standard engine, running at 350 revolutions per minute. The switchboard is of the Westinghouse standard type, and consists of seven polished white Italian marble panels. The general arrangement of the board is of the double-throw type. The engines are vertical single-acting, compound condensing machines. The cylinders are 18in. and 30in. in diameter and the stroke is 16in., taking steam at 150lb. pressure. The speed of these engines is 250 revolutions per minute. The boiler-room contains four Babcock and Wilcox boilers, each having a heating surface of 2,823 square feet and capable of evaporating under normal conditions 7,380lb. of water per hour at 150lb. pressure. The stoking is done automatically. The plant was installed by Messrs. Noyes Bros, of Melbourne and Sydney. The main shops which are supplied with electric power are the boiler, machine, and erecting shops, where the greater portion of the electricity is required for driving the metal-working tools. It is also used, but not to so great an extent, in the carriage and wagon shops, paint shop, ironfoundry, smithy, wheel shop, two sawmills, and the patternmakers' and forge shops.

The Italian Royal Visit.—The Council of the Institution took advantage of the presence of King Victor Emmanuel of Italy and Queen Elena in this country last week to present an address to his Majesty expressing recognition of the courteous and generous hospitality accorded to the members of the Institution during the visit to Italy in the summer. The deputation, which went down to Windsor by special train on Friday afternoon to present the address, consisted of Mr. Robert Kaye Gray (president), Lieut.-Colonel R. E. Crompton, C.E, R.E., Sir H. Mance, C.I.E., Dr. J. W. Swan, F.R.S., and Prof. Silvanus P. Thompson, F.R.S., accompanied by Mr. W. G. McMillan (secretary). The party was received in the Vandyck Room of the Castle, being introduced by Lord Kenyon (Lord-in-Waiting). The King, who wore Italian uniform, having shaken hands with the members forming the deputation, received the address graciously, and afterwards entered into general conversation, in course of which he disclosed an intimate knowledge of the progress of electrical and telegraphic science and engineering within his dominions. The address was in the following felicitous terms: "The Institution of Electrical Engineers in Great Britain having in the spring of the present year rendered homage at the tomb of the illustrious physicist, Alessandro Volta, and having visited the electrical railways, power stations, and works which form so noble a monument to Italian enterprise to-day, humbly beg permission to avail themselves of the present opportunity and to lay before your Majesty an expression of their recognition of the courteous and generous hospitality accorded to the members of this Institution, not only by their sister society, the Associazione Elettrotecnica Italiana, and by electrical engineers generally, but also by the various municipalities and corporations of the districts visited by them. The members of the Institution who were fortunate enough to visit your Majesty's dominions will never forget the genial kindness of their reception by the distinguished engineers and others whom it was their privilege to meet. During your Majesty's presence in England the President, Council, and members of this Institution respectfully tender an assurance of their devotion to the sovereign of a nation for whom they entertain feelings of the highest respect, admiration, and affection. We ever pray that the friendship and good feeling between the two countries, of which the warmth of our reception in Italy gave convincing proof, may continually grow in intensity, and that your Majesty may long be spared to guide the destinies of a nation to whom the people of this country are united by the bonds of an inalienable sympathy." Telegrams were dispatched the same evening to the Associazione Elettrotecnia Italiana and to the Milan Section of the Associazione, and the following replies have been received: "Most sensible to the feelings that inspired your kind telegram. I thank the Institution of Electrical Engineers for the new proof of sympathy, and return most hearty greetings in the name of the Associazione Elettrotecnica Italiana. (Signed) Ascoli." "Homage added by Institution of Electrical Engineers to enthusiastic reception to our king by all England was learned with grateful feelings by Milan Section Associazione Elettrotecnica Italiana as a new token of friendship binding scientific bodies of the two countries. (Signed) Bertini." Many of our readers, and more particularly their lady friends, will doubtless be interested to hear that amongst the Italian ladies who were presented to H.M. the Queen of Italy at the Italian Embassy last week was Mrs. W. B. Esson. Mrs. Esson's father bore the illustrious name of Giustiniani, and fought with Garibaldi in the cause of independence. The lady was born in Rome, and her mother was a Venetian.

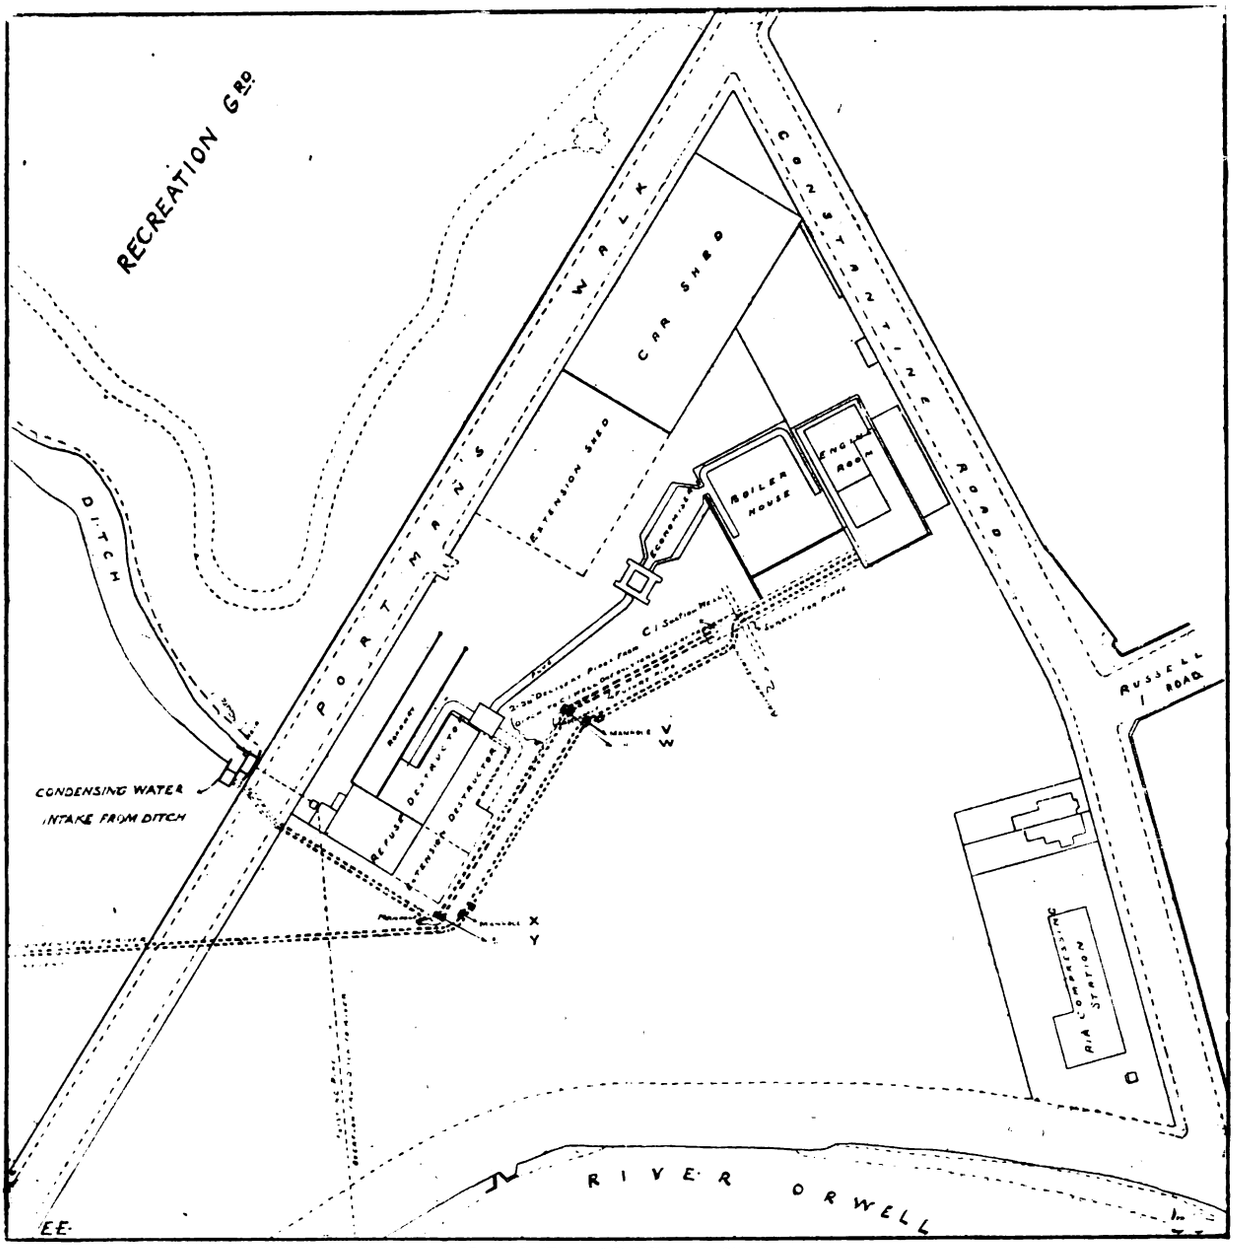
IPSWICH TRAMWAYS.

The formal opening of this system took place on Saturday, Nov. 21. We have taken part in many a function, but never in one so badly managed as this. The good people of Ipswich seem to think the representatives of technical papers are so badly off for a lunch that they will upon urgent invitation travel many miles to get one, and upon arrival find they must hunt through a large room to find if a chair is provided for them, like a hungry dog after a bone. The citizens of Ipswich will, in our opinion, long rue the day when this particular scheme was determined upon. Tramways are excellent things under certain conditions, but if the shopkeepers of Ipswich are not up in arms ere long they will prove more than human. The conditions in certain streets at Ipswich are altogether against the success of the scheme as carried out. These streets are narrow, so narrow that between tramrail and kerb there is not room for a cart or carriage or even a barrow. How the ordinary business of all these shops is to be carried on without interminable friction will puzzle the authorities. Probably the shopkeepers during the inception and early discussion of the scheme never realised what the end would be, and when their opposition might have been effective did not oppose—hence, we presume, will have to bear their loss as best they can.

In connection with this part of the question, however, the following report may have some importance. A case came before Mr. Justice Jelf at Manchester relating to the driving of a tramcar, and the judge is reported to have said: "Tramcars have no more right to the highway than I have, and the drivers must exercise reasonable and proper care. They had not the slightest right," he added, "to say to people, 'At all risks get out of the way,' but they must get out of the way themselves if the necessity arose." It is the general notion that under all circumstances other traffic must give place to tram traffic, but we believe the judge is right and general opinion wrong. The general conditions are that other traffic can, without loss or inconvenience, give place to the tram traffic; but we have yet to see tested the case where other conditions prevail.

It has been our good fortune to visit Ipswich several times recently and thus to examine the works during progress. The genial and energetic engineer (Mr. Ayton) was good enough on one of these occasions to visit with and describe to us the works, and there is no doubt but that the contracts have been carried out under his constant superintendence in an excellent manner. The detail drawings given herewith explain themselves, and will give a better idea of the works than any amount of words. It is sufficient to say that Messrs. Kennedy and Jenkin are the engineers and Mr. Peach the architect, in order to know that from the engineering point of view the greatest care has been taken to obtain an installation as perfect as knowledge and experience can make it.



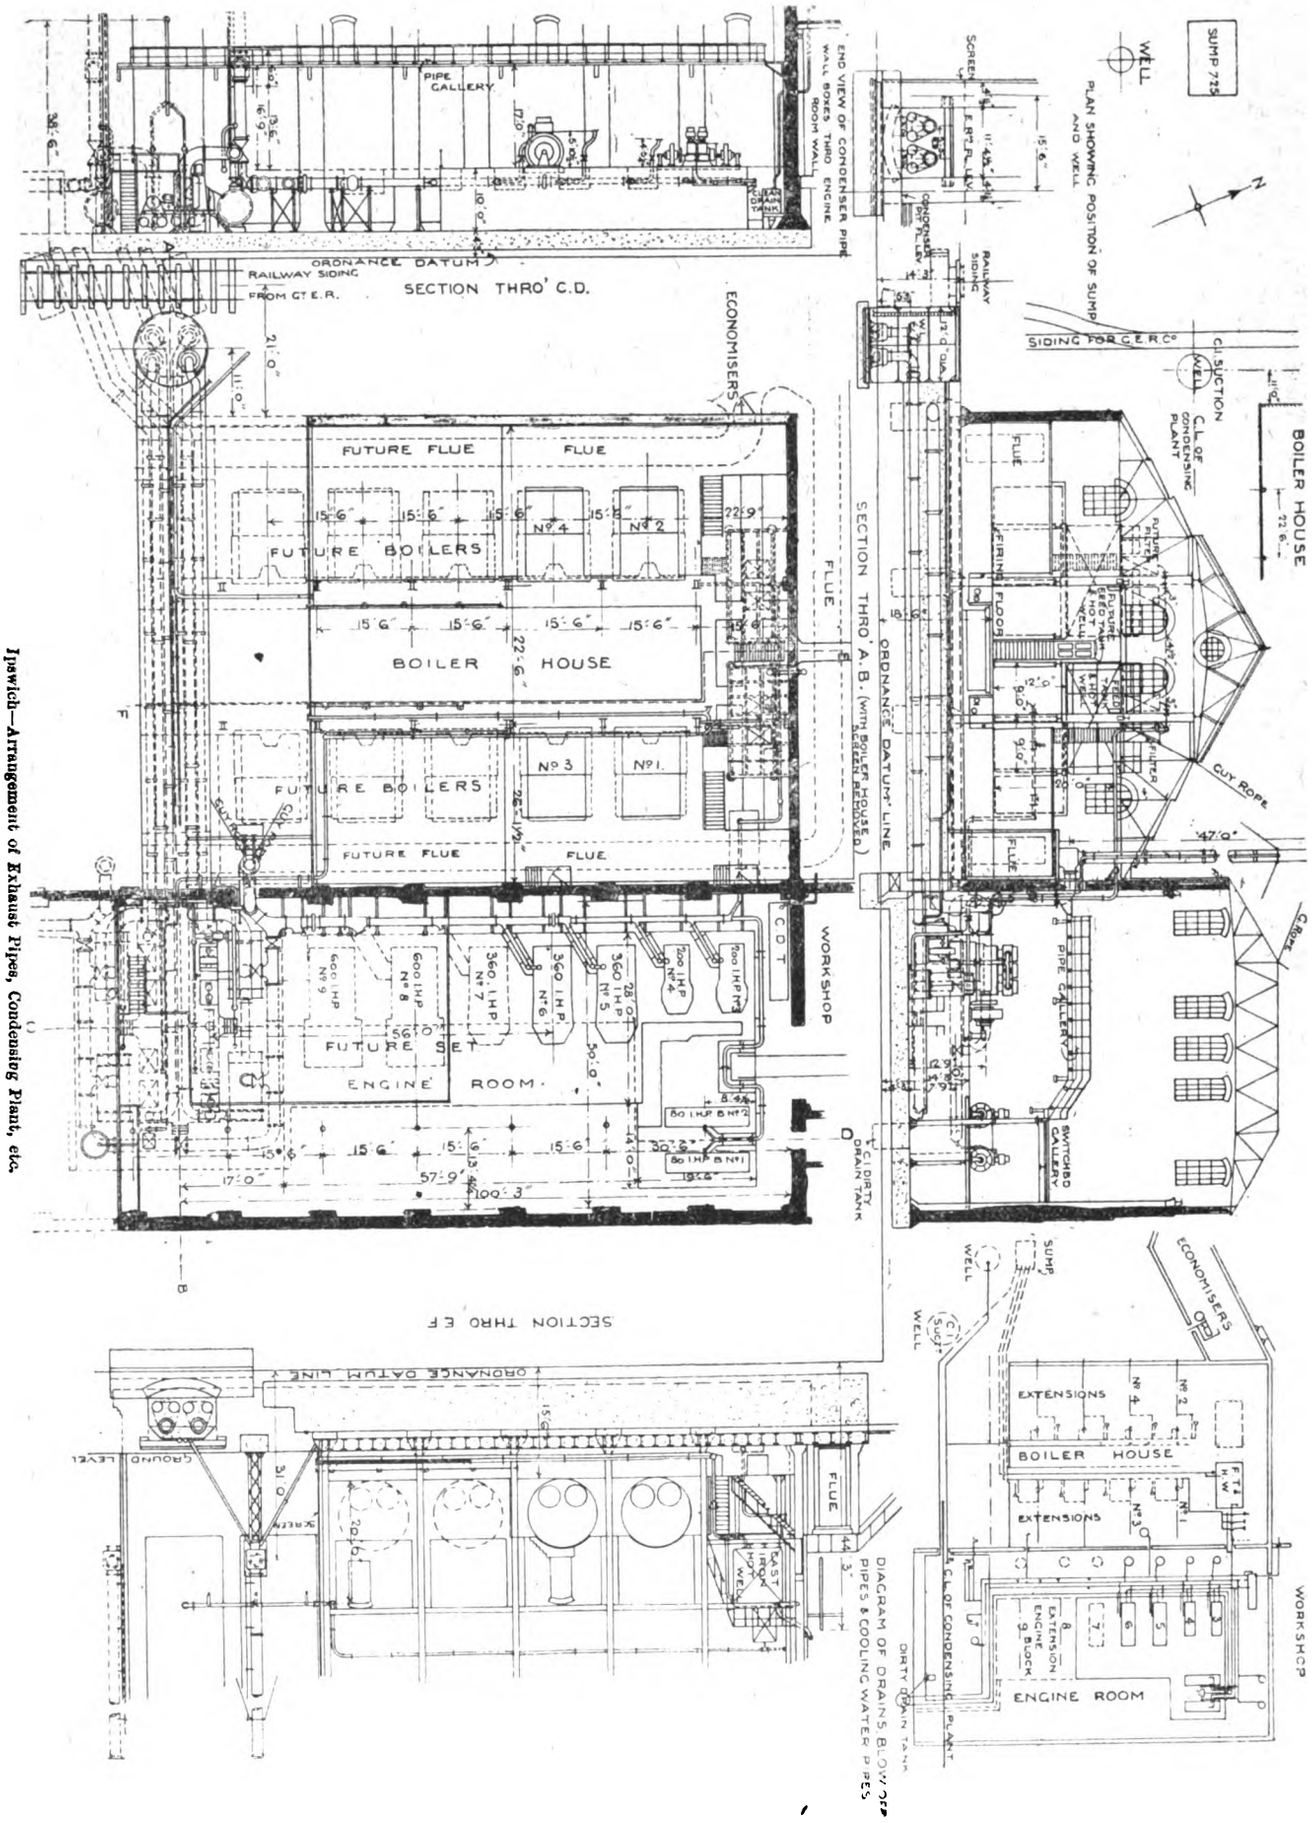
Ipswich—Plan of Buildings on Site.

Our illustrations show (Fig. 1) the plan of buildings on

Digitized by Google

the site. The contractor for the buildings was Mr. S. A. Kennay, of Ipswich, the amount of the contract being £26,948 for the generating station and £6,704 for the car-shed. In the latter are eight sets of rails for 40 cars, of which 26 are now in use. Figs. 2, 3, and 4 show details of arrangement of plant and lighting. It will be seen that the station is combined with a destructor, which is of the Meldrum Simplex type. The destructor and

shaft were built by Messrs. Shillitoe, of Bury St. Edmunds, who had a good deal of trouble with the foundation of the shaft. This is on a concrete base 46ft. square and 12ft. deep, with three layers of expanded metal embedded in the concrete. The shaft at the bottom outside is 21ft. 6in. across, and the walls are 3ft. thick. It is 178½ft. high, and is 12ft. square inside at the top, the wall at the top being 1ft. thick. The shaft is lined with firebricks

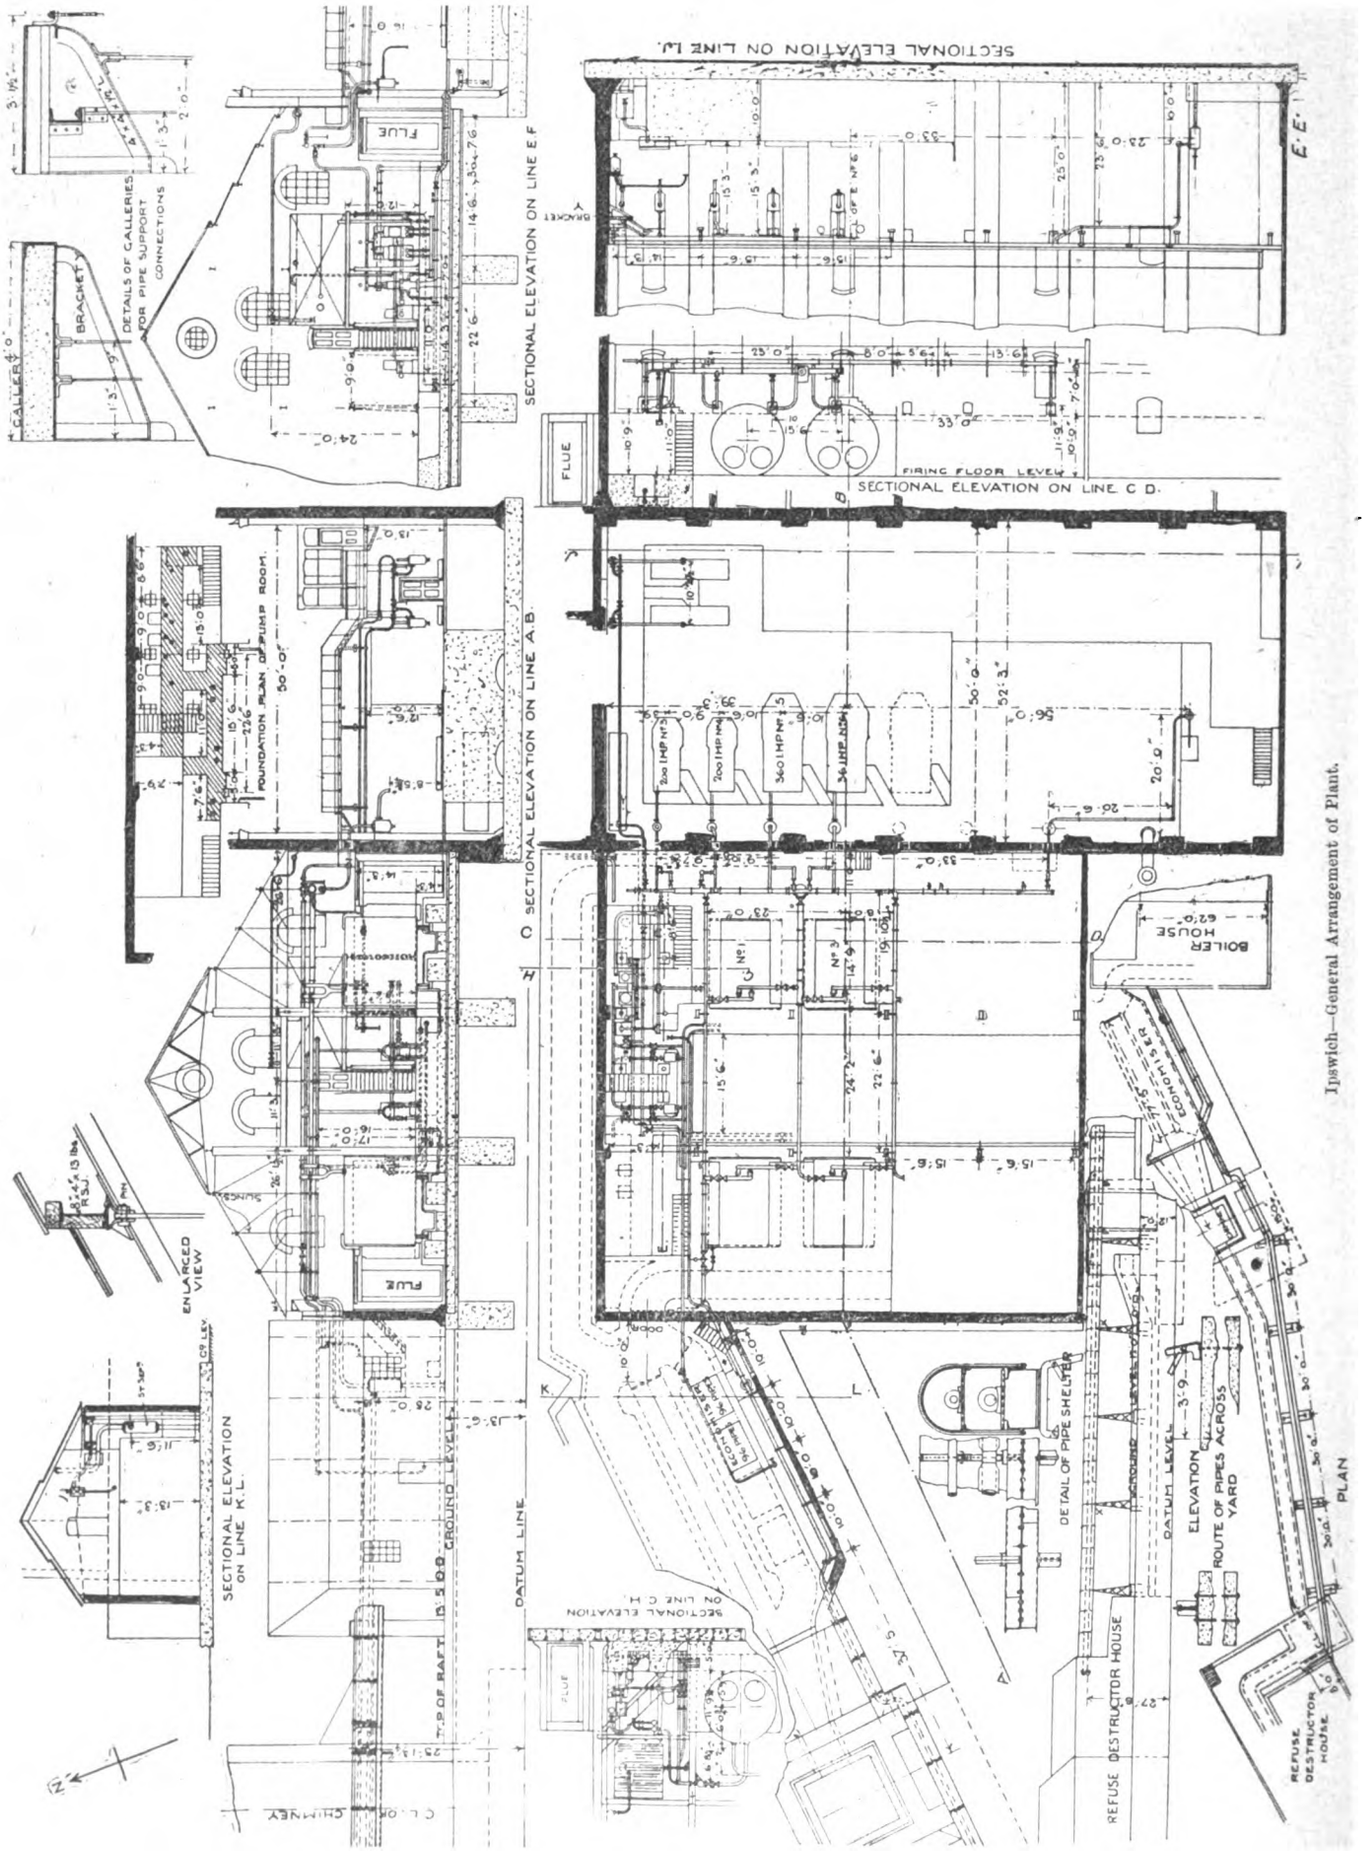


Ipswich—Arrangement of Exhaust Pipes, Condensing Plant, etc.

Digitized by Google

to a height of 97ft. above the top of the footings. The destructor buildings are of brick and corrugated iron. The tipping platform is approached by an inclined road-way from Portman's-walk. The refuse is shot down into a pit, from which it is shovelled into the destructor by hand. The destructor is worked by forced draught, and is connected with the shaft by a long flue on the opposite side to the flue from the generating station.

The boilers, by Messrs. Danks and Co., of Oldbury, are of the marine tubular type, 14ft. 9in. long and 11ft. in diameter. The combined engine and dynamo sets have Reavell engines combined with dynamos of the Allgemeine



Ipswich—General Arrangement of Plant.

Digitized by Google

Company's type, supplied by the Electrical Company. Messrs. Reavell and Co. have supplied in all six high-speed engines, the two largest capable of an output of 240 kw., two sets capable of 120 kw., and two balancing sets. The engines are all of the three-crank compound type, and can give 360 h.p., 200 h.p., and 80 h.p. respectively. The dynamos are for generating continuous currents. The two largest dynamos, for the tram work, are compound wound; whereas all the smaller ones, for lighting, are shunt wound.

Arrangement of Auxiliary Power Switchboard Ipswich—Elevation and Details of Switchboard.

The switchboard, the details of which are shown in Fig. 5, has been designed by Messrs. Kennedy and Jenkin, and supplied by the Electrical Company. It is divided into 21 panels of polished marble, on which the instruments are

Digitized by Google

mounted as shown in the drawing. The whole of the copper work on the switchboard is coated with tin. A battery of 124 cells, each cell with a capacity of 400 ampere-hours, has been supplied by the Tudor Accumulator Company. The steam pipes, exhaust pipes, etc., have been supplied by the Sir Hiram Maxim Electrical Company, who also supplied the surface condenser and pumps. Messrs. Johnson and Phillips have carried out the cable work both for the tramways and electric light. Messrs. Dick, Kerr, and Co. laid the permanent way, and this extends to something over 10 miles. In fact, the total length of single track is over 25,000 yards. The cars are of the single-truck double-deck type, capable of seating 50 passengers—24 inside and 26 out—and are supplied by the British Westinghouse Company, with the Brush Company as sub-contractors. The overhead equipment is by the British Electrical Equipment Company. There are 500 street poles 25ft. high above ground and 6ft. below, the buried part fixed in concrete. Section boxes are provided about each half mile of line.

INDEPENDENT TELEPHONY IN GREAT BRITAIN.

BY GARDNER AND HOLME.

(Continued from page 765.)

(6) Overhead Construction.

In the past and even present day, few engineers have realised the importance of good substantial overhead construction. An article appeared in a South of England newspaper only about a year ago stating that anyone could string up telephone wires, as they were as easily done as clothes lines. Such a statement confirms exactly what has been the general idea and practice of some for years, and which telephone users have found to their cost. There is no part of the whole undertaking requiring more care and attention and skilled workmanship than the overhead equipment, and if done well and good material used in the first installation, it will save constant interruption, repairs, and expense in maintenance. Bad overhead construction in a telephone undertaking shows up more than in any other electrical work, as the circuits are numerous, and when once put up necessitate very often the whole of the work being done over again, and at a much greater cost than if done well in the first instance.

Within large towns lately underground cables have done away with much of the overhead work, but being limited to the main, sub-main, and distributing cables, still necessitate the use of overhead circuits for distribution, in the form of No. 18 bronze wire upon insulators from distribution poles to the subscriber's premises. Entire underground distribution has been carried out in Glasgow and London within the central area, but this only to a limited extent, as the enormous expense involved in the laying-out of a system to provide for all business and private houses entirely underground makes it prohibitive, and there is no system yet designed that solves the question or commends itself. Overhead distribution from poles placed in the most convenient and accessible positions will be taken as the present everyday practice. These positions being obtained from private owners or placed on the local authorities' property, should be chosen as central and as near each group of subscribers' premises as possible, in order that the distribution of the wires will be equal from all directions, and the length of each circuit as short as possible.

In selecting poles for distributing purposes, the probable ultimate cable capacity should be allowed for in height, as the erection of a larger pole afterwards to accommodate more lines is a very expensive matter. The position should also allow of staying in three directions, but where this cannot be obtained the pole should be set deeper and surrounded with concrete and bracket stays fixed. Distributing wooden poles should invariably be of stout specification. Methods of staying will be described in junction construction. Very often great difficulty is experienced in the handling of these poles in erecting, owing to the crowded state and height of the buildings adjacent to where they are to be placed. In such cases it might be cheaper to distribute from an iron standard or pole, placed on one of the tallest buildings, or to carry the underground cable up to the side of the buildings, and distribute them from a pothead or junction box fixed to the building. In many instances where a number of subscribers are located in the same building, this is the best and most practical way of reaching them and least costly. Iron standards placed on roofs are not commendable, as it means (if extensively used) the opening up of trouble and expense in maintaining the roofs. Roofs upon which it is proposed to erect a standard ought to be carefully examined by a thoroughly practical workman, and even if sound ought to be braced and propped inside to prevent straining. In selecting and settling the positions for distributing poles great judgment should be used. It has been found from experience that to get the positions as near to one another and as near to the main cable as possible, in order to equally distribute the subscribers' overhead lines, is the best plan.

Fig. 27.

The sizes of the distributing poles and positions and wayleaves settled, the ordering forward and assembling of the stores, tools, and the general organisation of the work

Digitized by Google

can now be arranged. From the plan and schedule of the quantity of work to be carried out, the amount of stores necessary to order forward and the number of tools and

FIG. 28.

tackle to be provided will be obtained. As it is understood that the work is to be carried out to a price as arranged from the estimate and schedule of quantities, the workmen each day, this amount of work in calculation equalling the amount of wages paid as shown in Fig. 27.

The superintendent in charge of the gangs and who arranges the work each day should make it his special duty to examine and pass same and see that each gang of men are provided with all the necessary tools, tackle, and stores, and that precautions are taken to prevent accidents. He should also be acquainted with the condition of all plant necessary for carrying out the work, and be held responsible that ropes, blocks, ladders, and other tools, any failure of which might result in an accident, are maintained in good condition. He should make a periodic inspection and, when necessary, condemn and break up at once any plant or ladders showing signs of fracture. He should observe that all men placed under his charge are qualified for the work required of them. This will prevent many accidents, and ensure a better class of work being done. The qualifications necessary for ordinary wiremen are to understand perfectly the mounting and arming of wood and iron poles, fixing combiners, preparing soldering irons for use, seeing that firepots, poles, wires, tackle, and ladders are not left in any position in which accidents might be caused by them, and that open holes are never left unprotected, to be able to bind in and make off wires on insulators, solder same, and to have a thorough knowledge of all stores and material, and see that no work of a temporary character is done. First and second class wiremen should be well up in the preparing of tackle and understand the selection of positions for the erection, staying, and setting of ground poles and standards, running of wire, fixing of brackets and spikes to buildings, running and stapling of leading-in wires, testing and numbering out cables, making of potheads on distributing poles, testing out with battery and galvanometer, making off and soldering overhead wires to underground cables, examining and fixing earth wires to poles for lightning discharge, and be able to test out and repair faults. The foreman in charge of these men should be able to organise the work and see

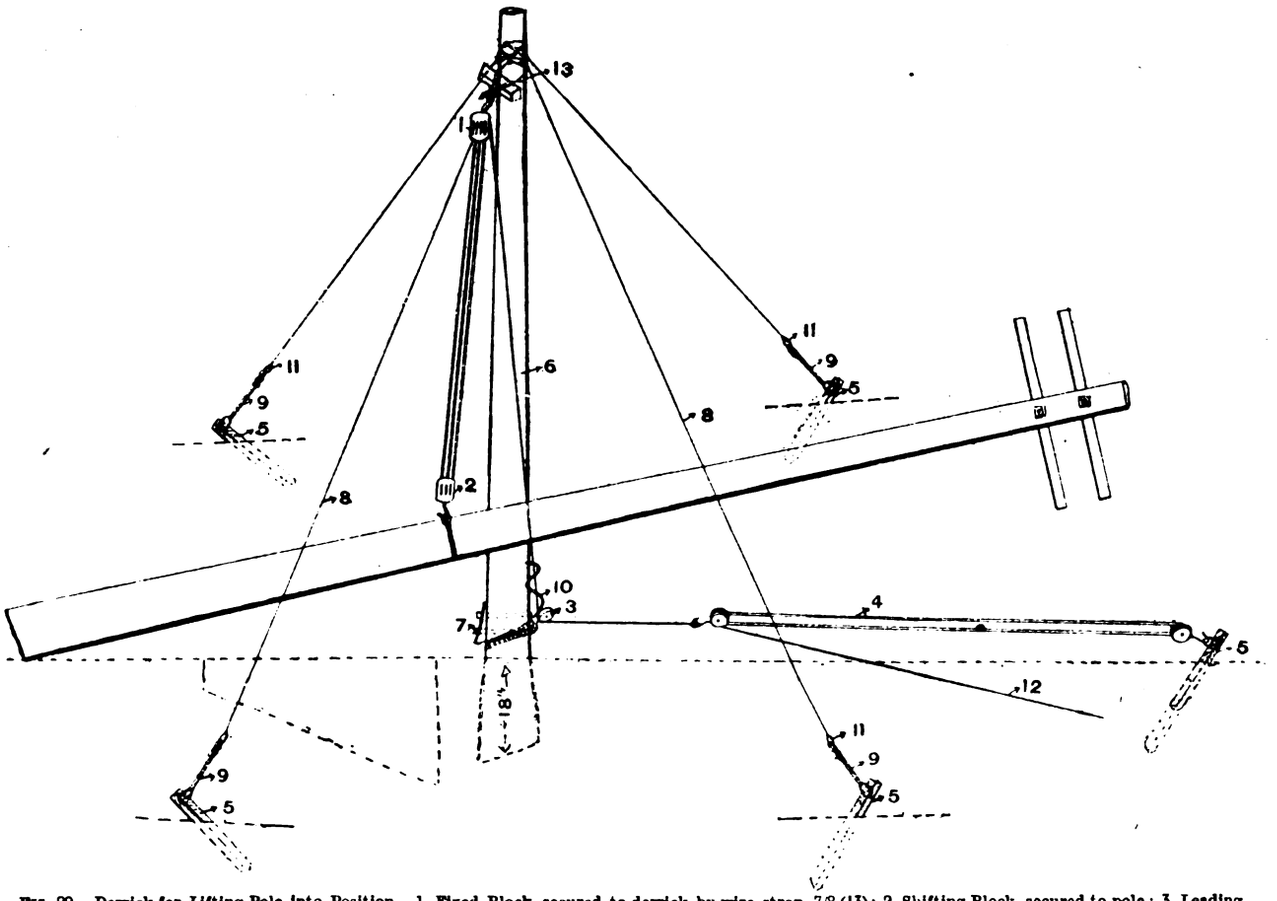

FIG. 29.—Derrick for Lifting Pole into Position.—1, Fixed Block, secured to derrick by wire strop, 7/8 (13); 2, Shifting Block, secured to pole; 3, Leading Block; 4, Luff Tackle; 5, 4ft. Holdfast. 2½in. by 2½in. T-iron with ring; 6, Derrick; 7, Chock; 8, Guys or Stays, ⅜in. flexible steel, fitted with eye for securing to holdfast; 9, 1in. Hempen Tail or Lanyard; 10, Stopper, for taking strain on fall of main tackle; 11 Eye; 12. Hauling Rope.

can be organised accordingly—that is, a number of gangs can be engaged and should consist of a first-class foreman, four wiremen, and two labourers to each gang. They should be organised to execute a stated amount of work same carried out thoroughly, be able to keep all records of work done, time-sheets and stores slips, understand all orders in reference to the receipt and issuing of stores and tools, prevent waste of material, and see all tools and

Digitized by Google

materials safely under lock and key and not left lying about, and keep his superintendent well posted up in the progress of the work under his charge.

Poles up to 50ft. can safely be erected by ladders and guys, as shown in Fig. 28, but for large distributing poles a derrick should be used. A diagram of the tackle is shown in Fig. 29. In preparing the tackle for erecting a large pole, the following method should be adopted. The derrick should be erected by ladders, and stayed temporarily with light lines of sufficient strength to bear the fitting up of the guys, stays, and tackle. This being done, the mounting and arming of the large pole can be going on as well as the digging of the hole. The derrick should be planted about 1ft. or 18in. from the deep end of the pole hole and about 18in. in the ground, being held in position by guys and stays. These stays are best made of flexible steel stranded wire rope, and made off with a spliced eye or thimble to receive the lanyard tackle, which in turn is fixed or made off on the ring of the T-iron bars driven into the ground. These bars are best made up of angle T-iron 2½in. by 2½in. by 4ft. long, provided with a ring of substantial make for attaching the lanyard. The stays can be made of permanent length to suit the raising of all sizes of poles, as the idea of having a lanyard is to take up or let out the spread of the stay. These lanyards should be of 3in. hemp rope, and able to take the strain of the whole pressure at any time likely to be put upon them. The heavy tackle is next fixed to a small arm, which should be permanently bolted to the derrick, about 12in. from the top, and the heavy tackle should consist of a two and a three way block for a rope, and fitted with a hook to take the chain sling, by means of which the heavy pole is lifted.

The tackle being in position and ready for lifting, the next step is to fit the leading block in position. This is done by means of a sling or chain round the base of the derrick and under the chock, the chock being used to prevent the sling slipping in an upward direction when the strain is taken on the tackle. The leading block should be what is termed a snatch-block—that is, a block with a movable outer strap—the bite of the running end of the main tackle being placed in this ready for hitching on to the luff tackle. The luff tackle consists of a similar make to that already described, but of lighter design, and is for the purpose of increasing the lifting power, as will be seen from the diagram. The usual method of securing the tail end of the main tackle to the luff tackle is by a Blackwall hitch. A relief guy or stay should always be at hand ready to take the place of one of the fixed guys, as often the fixed stays prevent the pole as it is raised from being brought to a vertical position; this additional stay can then be used to free the obstructing stay.

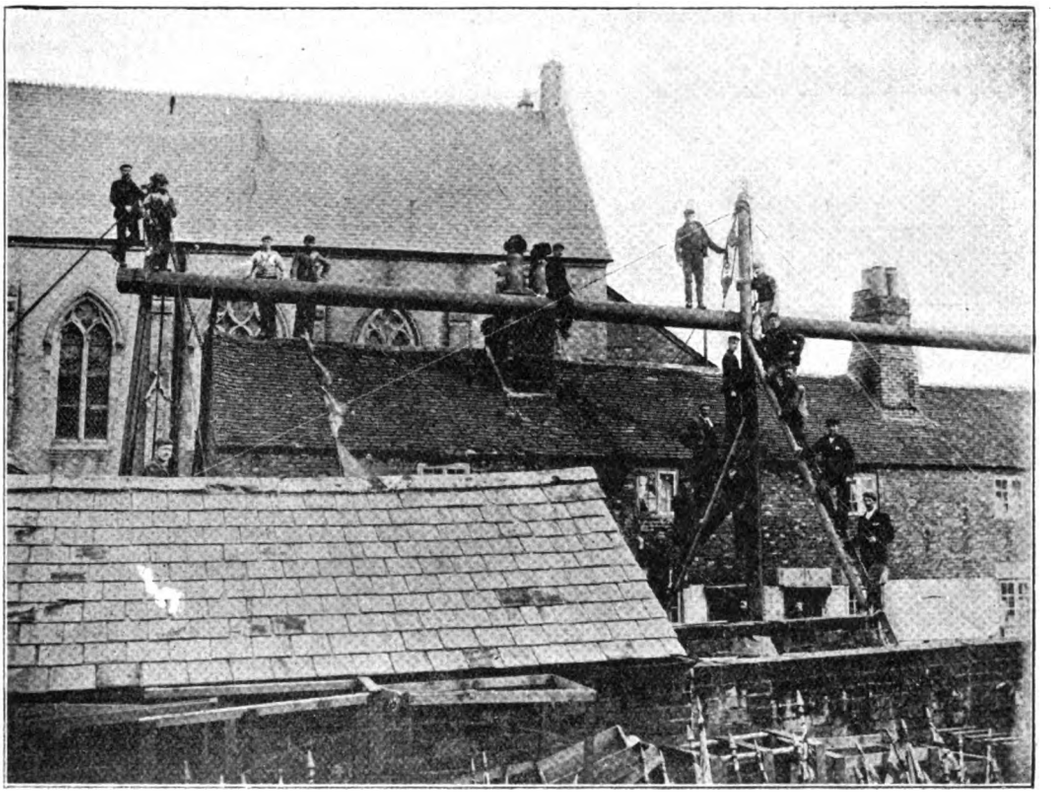

FIG. 29A.

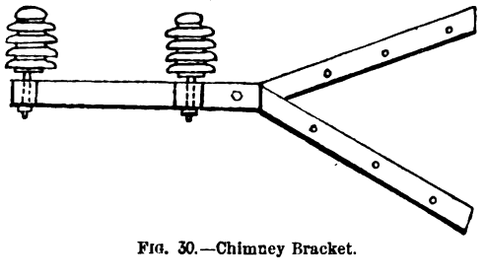

FIG. 30.—Chimney Bracket.

The poles being planted to the required depth, as a check upon this being honestly performed they are usually branded about 10ft. from the butt with a distinguishing mark, generally the local authorities' initials, and the dates of the month and year. Poles should always be set well against their work, for it is generally found when the ground sets the severe tension of the wires has pulled the poles upright, whereas if this precaution is not observed and the poles are set upright in their erecting the wires are almost certain to pull them over, and no amount of staying will bring them to the perpendicular. Arming and mounting poles should be placed in the hands of good men who are fitted for such, as, apart from the

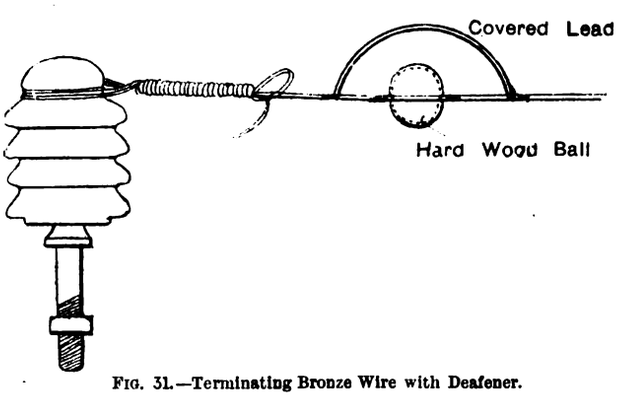

FIG. 31.—Terminating Bronze Wire with Deafener.

Digitized by Google

irregularity in regulating the wires, if the arms are fitted badly their appearance is most objectionable.

Staying.—The power of a line of wires to resist wind storms, and to maintain immunity from faults or irregularities, depends upon its strength and rigidity. It is not possible to provide poles of sufficient strength to withstand unaided all the stresses to which they are exposed without resorting to a method of staying or strutting. In order to obtain this, stranded wires of galvanised iron are used, or in the case of struts a creosoted pole. The upper end of the stay is fitted after the manner which will be described under the heading of junction lines, and the lower end attached to a stay rod fitted with an adjustable stay tightener in the ground, the rod in the ground being fixed to a large wood block of timber fixed firmly and rigidly so that a wind storm shall not affect the structure.

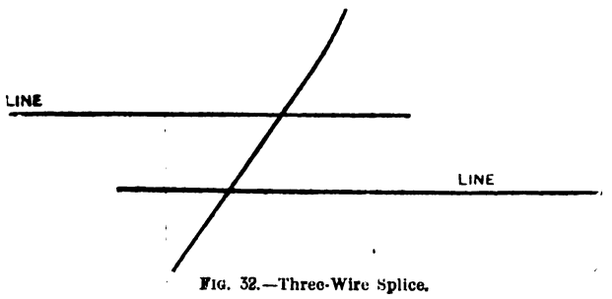

FIG. 32.—Three-Wire Splice.

Overhead Wires.—From the distributing poles to the subscribers' premises the overhead wires are run, and fixed to the chimneys or corners of the buildings by means of wrought-iron brackets or spikes, as shown in Fig. 30. To these brackets are fitted white porcelain insulators, preferably the pattern designed by Mr. A. R. Bennett, as they are in all ways more suited for telephone work than any other insulator, giving higher insulation and handier for making off wires. These insulators are for the purpose of preventing leakage and also supporting the wires. In attaching brackets to chimneys, the bracket should be fixed to the brickwork inside with the pull of the wires; if fixed away from the pull, an iron band should be placed around the structure or chimney. Roofs of old buildings should not be made use of for supports or brackets, as they form a source of endless expense. The foreman should in all

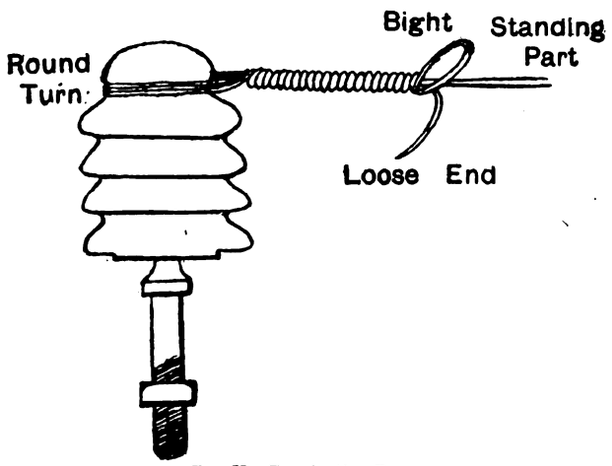

FIG. 33.—Terminating Bronze.

cases notify the owner or tenant, before commencing operations to fix his line, if the roof or structure shows any signs of damage. Wires should be kept absolutely clear of chimneys, lead roofs, or any such obstacles when first erected. One or two brackets will be found sufficient for each distributing line in a good underground system, and each insulator should carry its own wire, and each wire should be properly made off and soldered with bolt and resin to the insulated leading-in wire, which in turn is fixed by means of galvanised iron staples on the face of the building and run to the nearest inlet or window, the frame of the window being bored for the purpose of passing the insulated leading-in-wire through ready for connecting up to the inside apparatus. In the fixing of wires to buildings trouble is sometimes experienced through the humming noise, and several more or less effective methods of overcoming the difficulty exist. One plan is to bind in the bronze wires with strips of lead about ½in. wide, and twist the lead round the wires for a distance of about 12in. from the insulator. A better and more excellent method is to break the wires about 18in. from the insulators, and insert hard wooden balls doubly grooved for making off and terminating the wires, the continuity of the wires being made by bridging over the wooden balls with a piece of insulated wire. Fig. 31 gives a general idea of the method. It is inadvisable to cross power circuits or electric traction wires with open wires. These should be crossed at right angles and with special insulated wire, provided with a stranded steel core for attachment to the fixtures and the suspension and support of the insulated wires. In the running of bronze wires great care should be exercised in the handling. The wiremen should not be permitted to pay off with the hand, but should be instructed and made to use drums for the purpose, as if the wire receives the slightest abrasion or the skin becomes damaged it is sure to give way at the

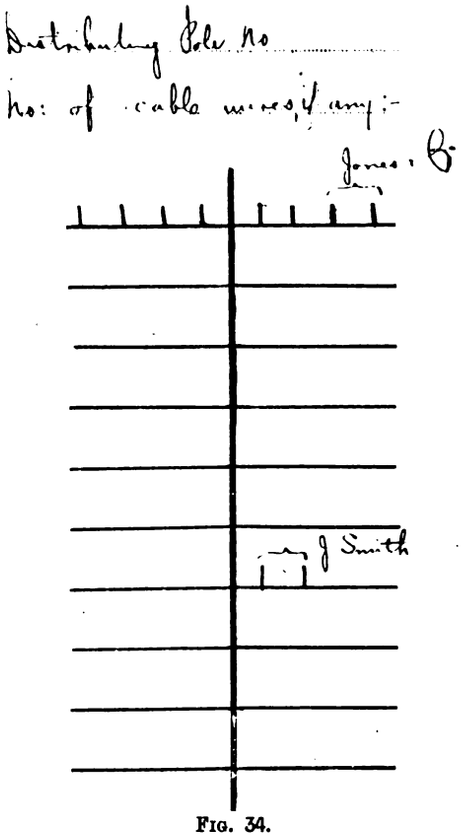

FIG. 34.

damaged part. The jointing of bronze wires should be done in the following manner: the two ends are laid together, overlapping each other, for a distance of about 9in., then twisted together in the centre position with a lay of about ½in. for a distance of 1¾in.; each end is then wrapped round the other wire for a distance of about ½in. The joint should be carefully soldered in the middle only. Soldering is most essential in all telephone joints, but many American engineers in place of solder make a joint which they consider it is not necessary to solder, and is known as the "three-wire splice." This is made by splicing in an extra piece of wire, as shown in Fig 32, after which it is finished the same as any other twist joint. It is much stronger, and is in our opinion better than the ordinary joint. In terminating or making off bronze wire, a length of about 30in. is allowed beyond the insulator, and at a point 12in. beyond the centre of the insulator the wire is doubled back on itself, the bite or loop thus formed being taken twice round the top groove of the insulator, and then bound tightly and closely round the main wire, as shown in Fig. 33. In running wires over roadways or across thoroughfares, watchmen should be stationed in commanding positions to warn drivers and passengers.

Numbering of Wires.—For the convenience of identifying working wires on distributing poles a diagram book should be kept (as shown in Fig. 34) giving all necessary informa-

Digitized by Google

tion. Too much care cannot be exercised by telephone men in the erecting of overhead wires, and the damage done to buildings over which the wire has been drawn should in every instance be repaired the moment it is discovered.

(To be continued.)

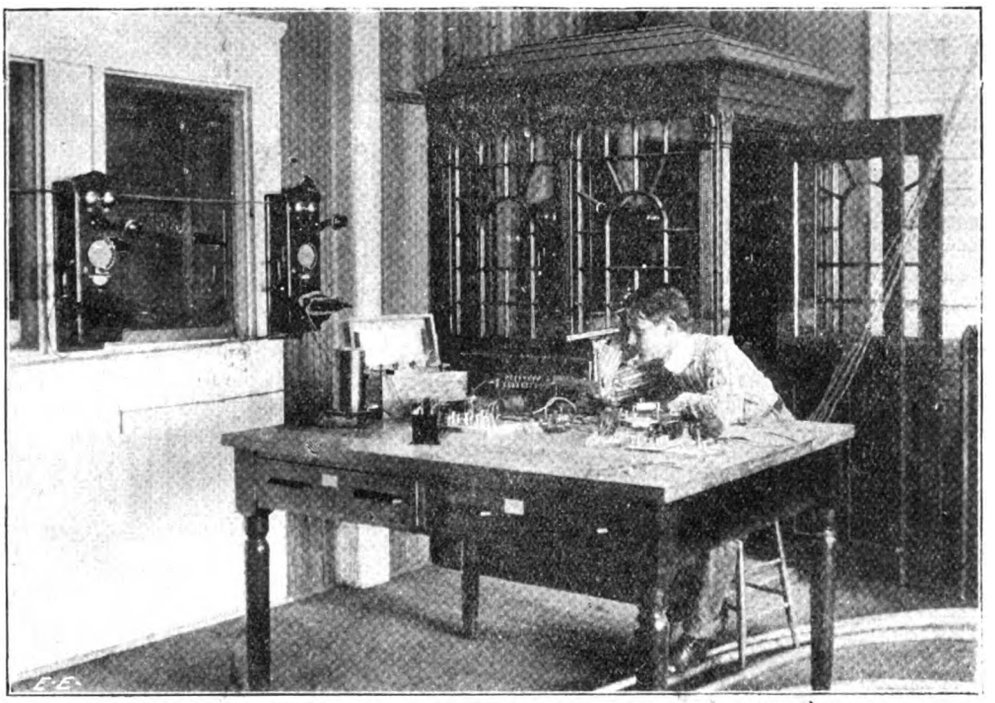

FIG. 1.—Sound-Proof Telephone Box with Cable-Testing Apparatus in Foreground.

TELEPHONE ENGINEERING AT PURDUE UNIVERSITY.

BY F. WELZ.

The great success which the American industry has shown in the last decade is largely due to the pronounced method of specialising which has taken place in the United States in all fields of business life. But not only that, the engineer and workman are exclusively specialists in their business, for the early education of the student is also more or less along special lines, this having been carried to a farther degree than is the case in Europe. The education which is given to an American student in his college differs very essentially from that which is given in England. The American high schools generally include large, prodigiously equipped laboratories, and a more practical education is given to the student than in England. These assertions are strikingly demonstrated by the fact that at Purdue University for more than two years a special school of telephone engineering has been created, and this is at present the only college in the United States where a special course for telephone engineers is given.

For the study of electrical engineering, generally four years are provided for. The future telephone engineers take the first two years together with the general electrical engineers, but in the third year the lectures on thermo-dynamics, mechanics, and steam engineering are omitted and are supplanted by special studies in the rudiments of telephone engineering. These special lines comprise lectures on telephone circuits, beginning with the old earth series system, continuing with the metallic self-restoring drop system and the now generally employed multiple common battery

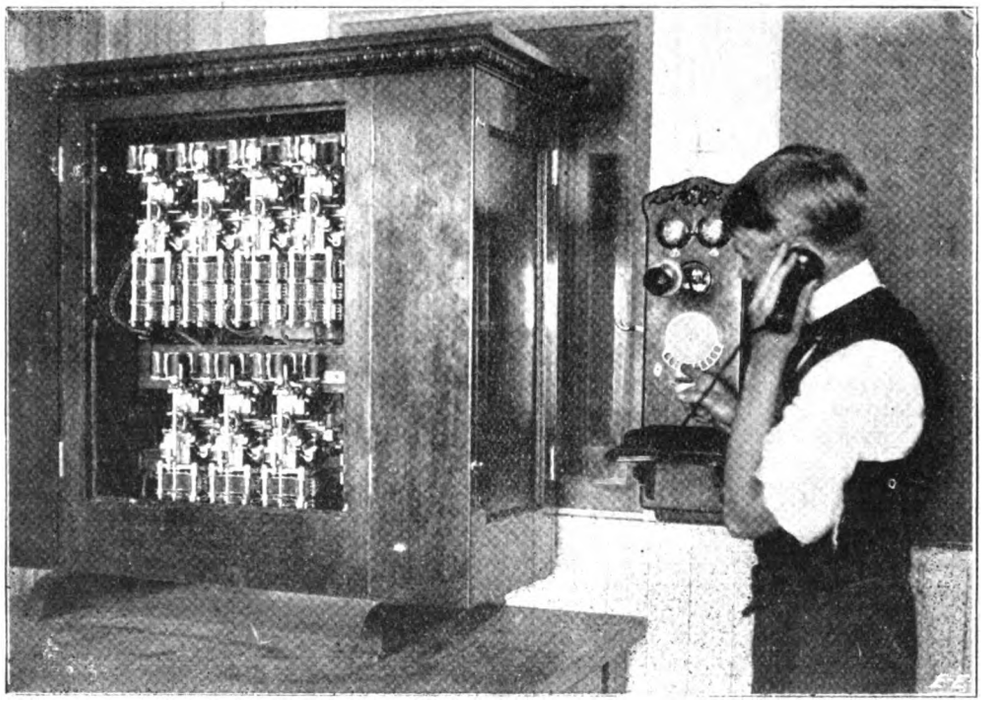

FIG. 2.—Strowger Automatic Telephone Exchange.

Digitized by Google

system. All metallic battery systems in use at the present time are elaborately discussed, and for six to ten hours a week the student has the best opportunity to take up in the laboratory the construction and the installing of telephone apparatus, testing telephone lines for grounds, resistance to earth, current and voltage conditions, and the locating of faults. Following this course of study, lectures are given on exchanges, apparatus for protection, signalling systems, and automatic exchanges. These lectures are also accompanied by well-selected work in the laboratory, dealing especially with the construction and manufacture of these apparatus. In the same year special lectures are given on acoustics, in which line special work is also done in the laboratory. In the last year follow studies of the different telephone systems, accompanied by the designing and laying-out of complete exchanges and telephone systems. The work in the laboratory comprises the more exact tests of cables, working relays, investigations on the variation of induction from one, two, and three phase alternating current of 104 to 9,000 volts, and effect of direct current of 110 to 500 volts, etc., upon telephone lines, etc.

The accompanying illustrations show the great importance which is given in the United States to the strictly practical side of the education of telephone engineers. The illustrations show (Fig. 1) the sound-proof telephone booth and a student testing cables, and (Fig. 2) the complete outfit of a four-party exchange of 1,000 lines ultimate capacity, system Strowger of the Automatic Electric Company. This system has been recently introduced on a very large scale in Berlin by the German Post Office Department. It is operated by a storage battery of 50 volts, and is subject to special investigations by advanced students.

The telephone laboratory of Purdue University also contains a 100-pair Roebling cable, 300ft. long, so arranged that it represents six miles of line capacity, and affords excellent facilities for measuring capacity and localising faults; a 20-pair switchboard cable, 500ft. long, used for ringing and transmission tests; and a complete installation of the Clarke automatic system; a Kelvin astatic galvanometer of 13,000 ohms resistance; Anthony 100,000-ohm box, different galvanometers, of d'Arsonval, Nalder, Rowland, Edelman, and a whole series of other laboratory instruments; a storage battery equipment, consisting of 10 cells of the Juilien type and 75 Chloride cells; a special 50-kw. 60-cyle generator, giving either monocyclic, two-phase, or three-phase alternating currents; a special high-tension switchboard, equipped with instruments and apparatus of the most modern type; a combined switchboard, having a total capacity of 920 double-connection plug terminals; a lamp board of 200 lamps, each lamp having separate terminals so that any range in the resistance from 1 ohm to 40,000 ohms can be obtained; a bank of 52 microfarad condensers; a high-voltage lamp board of 50 lamps and testing transformer of 10,000 volts; different apparatus for recording alternating curves, and a number of different machines and instruments. This shows without any doubt that great efforts are made to give the student not only a theoretical knowledge, but to make him a practical engineer. The necessity of creating such a special school for telephone engineers has been denied from different sides, but the success at Purdue University in the first two years does not leave any doubt in this direction.

There are at present 10 students in the fourth-year class who will receive their diplomas next June, 12 in the third-year class, and 43 in the two lower classes. The director of the department of electrical engineering at Purdue University is Prof. W. E. Goldsborough, at present also chief of the department of electricity at the World's Fair, St. Louis, 1904. The telephone section stands under Prof. T. R. Kelsey. It must be remembered that the telephone has found far more extensive use in the United States than in Europe, and not only all cities of any importance are connected by long telephone lines, but also large business houses and factories have their own private exchanges, and in the country we hardly find a farmer to whom a telephone is not an absolute necessity for his private and business life.

Litholite.

Messrs. Hunt and Hess, who manufacture this insulating material at 3, The Grove, Hackney, N.E., recently had a sample tested at the Westminster Electrical Testing Laboratory for insulation resistance and dielectric strength. Mr. L. W. Wild, the chief electrician at this laboratory, describes the results of the test as follows: "The sample consisted of a disc of 8½in. in diameter and 0·327in. thick. On receipt of the sample our first step was to paste on to each side a disc of tinfoil of 4in. diameter. A guard ring also of tinfoil was pasted round the edge of the disc to intercept leakage. We next measured the insulation resistance between the two discs, and obtained a figure of 67,000 megohms with a testing pressure of 1,500 volts taken from a battery. On disconnecting the guard ring the same figure was obtained, showing that surface leakage is negligible under normal conditions. The sample was next immersed in salt water for 24 hours, and after wiping off the surface moisture, but not otherwise drying it, we tested it again, and obtained 60,000 megohms with the guard ring connected and 600 megohms with it disconnected. In this case the surface leakage was some 100 times the leakage through the material, as might, of course, be expected. Next the sample was

Digitized by Google

left standing in a free current of air for three hours to dry, but was not baked. We then tested again and obtained 67,000 megohms with the guard ring, and 60,000 without it, the surface leakage being thus about 10 per cent. of the leakage through the material. The above tests show that the material is practically non-absorbive of water, has a high specific resistivity, which is well maintained after immersion in water, and although there is a certain amount of surface leakage when first removed from the water, yet this is soon stopped as the surface dries by natural means. The specific resistivity of the sample, from the above figures, works out to 6,550,000 megohms per centimetre cube at a temperature of 58 deg. F., and when subjected to a testing pressure of 1,500 volts. The dielectric strength was measured by applying an alternating pressure of 120 periods between the two tinfoil discs. The sample broke down with a pressure of 36,000 volts, having withstood 35,000 for a period of five minutes previously.

Rhodes Motors.

We have received a well-prepared list of the continuous-current R.E. type of electric motors made by the Rhodes Electrical Manufacturing Company, of Bradford. This company has its London office at 70 and 71, Bishopsgate-street.

We illustrate herewith one of these motors arranged with a back gear, so as to get a comparatively slow speed on the pulley. These gear wheels are stocked by the firm in a large number of sizes, so that they can give a great variety of speeds at short notice. The motors themselves, as illustrated in detail in the list, show evidence of careful design, and they are in conformity with the latest practice in continuous-current work. The motors are rated conservatively, so that they can stand a 25 per cent. overload for an hour without undue heating, and a 50 per cent. overload temporarily without sparking or injurious heating. The design of the motor is such that the one frame serves for the open and enclosed types, with, of course, variations in the possible output. The firm give at the end of the list prices both for the slow-speed and moderate-speed types, and we gather that they are stocked for several different voltages. No doubt, in this respect the firm will conform to the standards fixed by the Engineering Standards Committee, which were referred to recently in our columns. The firm would not be able to give the prompt deliveries which they guarantee were there not some limit to the range of voltages on which the motors have to work.

Portable Ammeter and Voltmeter.

The illustration herewith is of a combined instrument put on the market by the Union Electric Company, of 151, Queen Victoria-street. The instrument consists of a moving-coil ammeter and a moving-coil voltmeter mounted in the same case for convenience of transport, in order that tests may be made on installations so as to ascertain various electrical quantities. The voltmeter, for instance, can be used on three different ranges. In the first the whole of the scale corresponds to three volts, which is serviceable for measuring the

voltages on primary and secondary batteries. Under the second connection voltages from 0 to 150 volts can be measured, which is most useful when dealing with private plants and battery installations. With the third system of connection the extreme range is from 0 to 600 volts, which is intended for central-station work and for testing power distribution mains. The ammeter scale is divided into 60 equal divisions. The ampere-meter acts as a shunt across standard resistances, of which two are provided. With the first the meter reads from 0 to 30 amperes, and the second from 0 to 150. This instrument, if used direct on circuit of low voltages, can measure down to one-thousandth of a volt. With the two instruments and a six-cell battery, insulation resistances up to 500,000 ohms can easily be measured. The price of the whole set is exceedingly moderate, and should command for it a ready sale amongst contracting engineers.

Pamphlets, Catalogues, etc., Received.

INDUCTION MOTORS, enclosed arc lamps, oil switches, overhead trolleys, electrical measuring instruments, type K single-phase integrating induction wattmeters. The British Thomson-Houston Company, Limited.—Additions 155-158, 160, and 161 to general catalogue; illustrated and descriptive.

IMPROVED WALL PLUG. Illustrated. The Improved Plug Company, 45, Upper Jackson-street, Manchester.—Describes a patented wall plug which provides a ready and efficient means, mechanically correct, for an unskilled hand to plug a wall in a sound and neat workmanlike manner, at a price considerably less than the old-fashioned method. Serviceable to electricians, telephone and bell fitters, plumbers, gasfitters, furnishers, etc., and for household requisites.

PATENT PHŒNIX ELECTRIC HEATING APPARATUS. Illustrated. The Electric Heating Corporation, 34, Leadenhall-street, London.—The corporation state that they are prepared to arrange with central supply stations for the supply of patent Phœnix heaters on special terms. They have in preparation a list of cooking apparatus, hot-plates, and flat and curling irons, foot warmers, etc.

PERSONAL.

We have to congratulate Mr. Bertram Hopkinson on his appointment to succeed Prof. Ewing in the chair of Mechanism and Applied Mechanics at Cambridge.

Mr. Alfred Rosling Bennett, who has acted as general manager and engineer of the Glasgow Corporation telephone department since its establishment, has intimated to the committee that, owing to the many claims upon his time entailed by his outside duties, he wishes to retire from the general managership. The Telephone Committee recommend that Mr. Bennett continue in his present position until the close of the financial year, and that thereafter he be retained as consulting engineer; that Mr. John Macfee, who has been throughout the assistant manager, be appointed general manager; and that Mr. John MacCallum, who has hitherto held the office of cashier, be appointed assistant manager as well as cashier.

Mr. W. H. Grimsdale, the chief engineer of the Warrington electricity department, and manager of the electric tramways, has resigned upon being appointed to superintend the electrical equipment of the Government dockyard at Portsmouth.

Mr. R. C. Coxon, of Sunderland, has been appointed general clerk at the electricity works, Bermondsey, at a salary of £104 per annum, and Mr. H. Atkinson, of York, has been appointed as switchboard attendant.

Mr. H. T. Strugnell, who has been employed temporarily as storekeeper at the central electric generating station, Battersea, has been placed upon the staff at a salary of £91 per annum.

With reference to the appointment of assistant electrical engineer at Oldham, we are informed that, Mr. S. H. Rhodes having withdrawn, Mr. H. A. Brimelow, of Bolton, has been appointed.

NEW COMMITTEES.

BARNSTAPLE.—*Electric Lighting*—Aldermen Aston and Young; Councillors Richards, Lindsley, Youings, Hopper, Cooke, and Andrew; the Mayor (Councillor H. Barrett), chairman.

BATTERSEA.—*Electricity*—Mr. W. Rines, chairman.

DONCASTER.—*Electricity*—Alderman Abbott; Councillors Bennett, Clark, Dowson, Halmshaw, Kay, Manwaring, Smith, Steel, Tuby, Wightman, and Windle.

GRAVESEND.—*Electric*—Aldermen Russell and Wood; Councillors Byrne, Enfield, Rhodes, Archer, Davis, Prevost, Schultz, Cosh, Smith, Sandford, and Berkowitz.

GRIMSBY.—*Electric Lighting Sub-Committee*—Alderman Dobson, chairman; Councillor Alward, vice-chirman; the Mayor (Councillor Colonel Bannister); Aldermen Brocklesby and Evison; Councillors Brown, T. King, Maddison, F. Moss, T. C. Moss, Riggall, Simons, Tickler, Wharton, G. A. White, Jackson, and Pickwell.

OXFORD.—*Tramways*—Alderman Salter; Councillors Cannan, Carter, Dodd, English, Higgins, Jackson, H. S. Kingerlee, Le Mesurier, Maunsell, Salter, Taylor, Twining, Underhill, and Sherwood.

RAWTENSTALL.—*Electricity and Tramways*—Alderman Trickett, chairman; Councillor Compston, vice-chairman.

ST. MARYLEBONE.—*Electricity*—Councillor E. R. Debenham, chairman.

SWANSEA.—*Tramways and Electric Lighting*—Mr. A. Sinclair, chairman; Mr. David Davies, vice-chairman.

WEYMOUTH.—*Electric Lighting*—The Mayor; Aldermen Whettam, Lovell, Bagg, and Morris; Councillors Honebon, Bridle, and Bennett.

WOOLWICH.—*Electricity*—Aldermen Macnamara, Robson, and Tynemouth; Councillors Adshead, Baglow, Calderwood, Elms, Fennell, Ledger, Merritt, Mitchell, Sheppard, J. Turnbull, J. A. Turnbull, W. Turner, and Widger.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to July, 1903, now ready.*

BAD BUYERS.

Amongst the many interesting questions which have been raised in Mr. Joseph Chamberlain's speeches on the fiscal policy of this country, is that of the real advantage to the country of importing foreign goods in order to save comparatively small amounts in first cost. Any such argument in the abstract is much enhanced by quoting special instances, but in so doing the figures given are often open to criticism in detail quite apart from their general bearings. It will be remembered that, speaking in Newcastle, Mr. Chamberlain referred to the purchase of Belgian tramrails by the London County Council. His argument was that the saving made was small as compared with the larger amount of remunerative labour which would have been employed if these rails had been manufactured in this country. The actual figures given as to the saving in first cost on the total expenditure of forty-one thousand pounds were incorrect, as has been shown by Mr. J. W. Benn, the chairman of the London County Council Highways Committee. This disagreement over the figures raises a side issue with which we now propose to deal. Thus, referring to the subject in his speech last Friday at Cardiff, Mr. Chamberlain says that if there was the large difference of eight thousand pounds between the English and foreign tenders, the County Council "must have been very bad buyers, because I was buying rails at the same time in very large quantities for one of our great Colonies. I had to give an order for about one hundred thousand tons. The difference between the lowest price at which Germans and Americans would put the rails and the price which I obtained in tender from English railmakers was only something like five shilling per ton, and that certainly would not make a difference of eight thousand pounds on a purchase of thirty thousand pounds' worth of rails. I have come to the conclusion, therefore, that if the County Council buy all their goods without taking a little more pains to give the opportunity to English firms to tender, probably their undertaking will be less profitable than it might." In reply to this speech, Mr. Benn has stated in a letter that English firms had every opportunity to tender, because the matter was fully advertised in the leading trade journals and newspapers, and that three or four of the leading British railmakers tendered. The fact that only three or four British firms took the trouble to send in their prices for these rails is evidence that the London County Council is not highly esteemed in this country as a buyer of materials. A few months ago the same thing was in evidence when the Council were advertising for structural steelwork. In that case complaint was made that English firms either refused to tender or required too long a time to complete the work. The conclusion to be drawn is not one which is complimentary to the Council, but it is the natural outcome of the trading policy which they have pursued. This subject of the relations between the buyer and the seller is one which is intimately connected with the economical carrying out of work. It is in few cases that the actual cost of materials supplied is so closely connected with the contract sum as in the supply of steel rails. In the majority of cases with which our electrical contracting firms have to deal, there arise in fixing the contract sums questions of sub-letting of portions of the work, the erection of the plant, etc. These items introduce risks which are intensified by the standard clauses of the London County Council, which often would, if adhered to, call for the disorganisation of the working arrangement of a firm when carrying out the contract. Another point is that the lowest tender is usually accepted, as

Digitized by Google

it requires an extremely strong technical man to carry through not only his departmental committee, but also through the Finance Committee and the whole Council a recommendation to accept a tender high up in the list on grounds which may not be appreciated by the individual councillors. The result is that contractors are not keen to take work at extremely low competition rates accompanied with the many risks entailed by the standard labour clauses of the Council. These clauses are practically inoperative abroad, with the result that while framed to assist the English working-man, they have the effect of sending work on which he depends for a livelihood out of the country. We are not in any way blaming the Council for accepting a foreign tender which shows a large saving in first cost, as the reasons for and against this are yet to be thoroughly investigated. We do blame them, however, for their short-sighted business policy, which prevents their being able to buy on even as favourable terms as a Government department. The opposite extreme, as far as buying is concerned, we take to be that of our great railway companies, who have not yet found it advantageous to go abroad for their supply of steel rails.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE AIM OF A SCIENTIFIC INSTITUTION.

SIR,—It appears to me that Mr. Gray's remarks regarding the proper scope of the Institution of Electrical Engineers have been, to some extent, misunderstood by the electrical Press.

I would, at any rate, venture to express my own view on the subject with every deference to those who differ with me. In my opinion, an Institution of Electrical Engineers should, in accordance with the terms of its charter, be all-sufficiently concerned with the technical work of an electrical engineer, leaving the business side of all questions in the hands of those who are responsible for the administrative and commercial working of their respective electrical undertakings. I am quite ready to admit that more often than not the successful engineer is successful because he possesses a business mind, or has had a commercial training. That, however, is no argument against a separate association for dealing with the business aspect of things electrical, and anyone who is serving in the double capacity of director (or manager) on the one hand, and engineer on the other, would naturally seek attachment with both headquarters.

I venture to suggest that a great deal of the work that certain prominent members of the Institution are engaged over in connection with pressing claims for revising legislation and suchlike, is far more connected with their interests as business men than as engineers, and that as there is an abundance of such work ahead, it would be as well if a separate body were formed to attend to it.

The very constitution of the Institution shows that its work is really strictly technical. Thus, those who are only associated with electrical work from a commercial point of view are classed as associates; yet obviously these, rather than those who have attained academic or technical distinction, are the most suited for urging legislative reforms. Again, it has been suggested that the proposed tariff reforms should be discussed in their relation to electrical work, but here, again, surely those who would be best adapted to represent the Institution are the "men of affairs" rather than those who, as distinguished engineers or electrical *savants*, are prominent members of Council or vice-presidents.

Tariff reform on an Imperial basis is a subject I myself have been very deeply interested in for a number of years, but not as an electrical engineer, any more than as a mere consumer of bread, and I should certainly not look to an Institution of Electrical Engineers for taking the matter up. On the other hand, I should expect an association concerned with the commercial aspect of electrical undertakings to enquire into the matter in connection with their interests, and with useful results.

We might surely do worse than note the way such institutions as the Institution of Civil Engineers regard the difference between technical (or scientific) work on the one hand and business on the other.

Certainly, if a "temple of engineering" were ever to be realised, that, as a sort of enormous trades union (of the right type) to guard and agitate the interests of all the trades concerned in any form of civil engineering—mechanical, railway, electrical, etc.—would be the most suitable channel for dealing with reforms associated with the business, as opposed to the technical side of electrical work. Meanwhile, there would appear to be ample scope for an association to take up the interest of "commercial electricity" as distinct from the interest of those who, as engineers, *render* electricity a subject of commerce. I am aware, however, that a new body such as I speak of would, at first, be open to the objection of carrying less weight in mass, but it would be more in accordance with reason.—Yours, etc.,

CHARLES BRIGHT.

31, Old Queen-street, Westminster, Nov. 24.

STEAM TURBO GENERATING PLANTS.

SIR,—While I am quite able to defend and maintain my position on the above matter, provided the controversy is carried out on fair and legitimate lines, I beg to protest strongly against the tactics resorted to by Messrs. Belliss and Morcom, Limited.

In the first place, although at the outset of my last reply I frankly accepted the correction they made as to the steam consumption of their Leeds engine as given to me by the city electrical engineer (trivial though that correction was), and also expressly declared that the figures given in my paper were, to the best of my knowledge, correct, Messrs. Belliss calmly ignore these facts, and insert the following inaccurate statement in their letter: "We called the statements extracted from his paper misleading because these incorrect statements were largely used in his argument. As he does not in his reply dispute the inaccuracies (*sic*), the previous letter still applies to the facts." After this apparently wilful or careless neglect of facts, I trust Messrs. Belliss will cease to make reference in general terms to alleged inaccuracies on my part unless they point out exactly where the inaccuracies are.

The difficulties which Messrs. Belliss suggest with regard to working turbines with steam superheated within practical and economical limits are purely imaginary, and appear to indicate a very restricted knowledge, indeed, of the subject under discussion; perhaps it will be useful to state for their information that the clearances in the turbine are arranged to allow for expansion due to superheat, and if, on occasion saturated steam is used, the economy is not let down to any greater extent than in the case of reciprocating engines designed to run with superheated steam, running on saturated steam, and probably not so much. Exactly what is meant by the "maximum possible superheat," I am unable to say, but it is an undoubted fact that turbines give no trouble when working with superheated steam, whereas the troubles with reciprocating plants on high superheats are many.

It is true that I prefer to compare results "under actual daily working conditions" and to have "the outcome of every-day practice," but the table given in the letter gives neither one nor the other; there are so many additional factors controlling the figures given therein as to render them valueless and irrelevant to the subject under discussion.

I will, however, submit a proposal to Messrs. Belliss which is quite relevant to the present controversy—viz., that Messrs. Belliss select any 300-kw. alternating-current plant running on superheated steam and driving its own condensing plant, and of which they have manufactured the engine. The plant selected shall have been in daily work on a lighting or traction load for the past two years without any renewals or repairs to the pistons and valves. This plant to be tested on full, half, and quarter loads by an independent engineer. I will arrange to place a steam turbo set of the same output, and which fulfils the

Digitized by Google

same conditions, at the disposal of the same engineer for a like test, and the steam consumption per kilowatt output on both tests shall be published in the technical Press. It shall be a condition of this contest that both Messrs. Belliss and myself shall have representatives present at the tests.

In conclusion, will Messrs. Belliss say what extra clearance they give piston valves for 600deg. F. superheat?—Yours, etc., GEO. WILKINSON.

"THE PHIELASHOK."

SIR,—I notice in your last issue that exception is taken by Messrs. Oliver and Co. to my remarks concerning their "Phielashok." I have read their letter with interest. I may state that I only understood the method of applying the instrument as was given by the illustration itself. Surely one hand is there shown actually placed upon one of the fittings. Why Messrs. Oliver and Co. are surprised at my drawing attention to this I fail to see.

I still claim that the method, as shown, would be positively unsafe in a great many of our large installations. I will admit that if two "Phielashoks" were used (one in each hand) then the operator might be safe, but I am not aware that Messrs. Oliver and Co. have pointed this out.

It is incorrect to think that I "apparently would place a hand *directly upon* any terminal that may be alive." Reference to my letter will show that I am opposed to this, and in no slight measure. The makers also say that it was for earthed systems that the "Phielashok" was especially designed. Again, I think they have missed their point and seized mine, for I did not notice that the instrument was especially adapted to earthed systems.

By the way, I do not wish to make it appear that the use of the instrument would be attended with any more danger when used on a system consisting of one insulated conductor and earth return than when used on one consisting of insulated metallic return. The danger referred to is when that *which ought to be* an insulated system *has an accidental "dead earth"* on one pole, for the full potential then exists between the *other pole* and earth. This may occur at any time suddenly and *without warning*. In conclusion, I may say that I have never used a "Phielashok," nor even heard of such an instrument before.

As to my electrical susceptibility I cannot exactly state, but I dare say my medical man would be willing to present his certificate, especially if it will be of any assistance in the design of an instrument particularly adapted to my physical system. However, jokes aside, I wish to thank Messrs. Oliver and Co. for their offer, which I shall be extremely pleased to accept. Our voltages are respectively 220 and 240, direct current. But what am I to do with the other hand?—Yours, etc., J. ISAACS.

11, Highfield-terrace, Somerby-road, Grantham,
Nov. 23, 1903.

APPOINTMENTS VACANT.

Engine-Room Attendant. Salary 35s., rising to £2 per week. Particulars from the Secretary, South-Western Polytechnic, Manresa-road, Chelsea, S.W.

Shift Engineer, Tunbridge Wells, £100 per annum.

Tramways General Manager, Sheffield Corporation, Dec. 1.

Engineering Assistant, used to tramway work, Finchley Urban District Council, £175 per annum. Application by Dec. 3.

Assistant Electrical Engineer, Sanitary Commissioners, Gibraltar. Salary, £200 per annum. Applications by Dec. 16. See advertisement in last issue.

Under-Foreman, electric repair shop. See advertisement in last issue.

Armature Winder, Blackburn Tramways Depôt, Nov. 30.

Tramways General Manager, Bolton. Salary, £500 per annum. Dec. 4.

Traveller with connection amongst buyers of arc lamps and switchboards, Box 808, *Electrical Engineer* Office.

Junction Box Fitter, used to fitting house fuse boxes, Box No. 909, *Electrical Engineer* Office.

Cable Jointer, York Electric Lighting Station, Dec. 7. See advertisement.

DESTRUCTOR AND ELECTRICITY STATIONS IN SMALL TOWNS.*

BY S. D. SCHOFIELD.

Electricity supply in small towns has not made the progress that one might have expected, though within the last few years a number of stations have been started where the refuse of these towns is destroyed by fire in special furnaces, and the steam raised by this heat is utilised for driving dynamos for lighting and power. Opinions differ as to the wisdom of this combination, varying from the extreme at one end, which is the view that a destructor station is a veritable gold mine, where steam can be raised *ad lib*, driving electric generators producing an unlimited supply of energy, sufficient to light all the streets of a town, propel all cars, supply all private lighting, and drive all the motors which may possibly be required, to the view that, at its best, a destructor is an unmitigated nuisance; and if the electrical engineer of the town is your bitterest enemy, you will have satisfaction, indeed, if you can arrange for the destructor to be tacked on to the electricity supply station.

First and foremost, it must be understood that the destruction of refuse is a purely sanitary matter, and under no circumstances may that work be jeopardised for the sake of power production. However, the modern high-temperature destructor may be used for steam-raising without any fear as to that use being a cause of nuisance. The higher the temperature of the furnace, the less will be the risk of any noxious gases escaping into the atmosphere, and the higher will be the duty of the plant. Any of the leading makers will erect plant capable of destroying the refuse of a town without any nuisance, and without any dust being allowed to escape from the chimney, giving a guaranteed evaporation of 1lb. to 1½lb. of water for each pound of refuse destroyed, according to the value of the refuse. A test at Cleckheaton, on Oct. 9, 1903, shows that during a run of eight hours, 51·7 units were generated per ton of refuse destroyed.

In January, 1902, at Shipley, during a run of one month, 37·4 units were generated per ton of refuse destroyed, and with a similar plant at Wrexham 37·8 units per ton of refuse were obtained at a test of the same duration. A further test of the value of refuse may be obtained from the accompanying Table A, giving the results of a three weeks' test of the steam-raising plant at Shipley, the first week with the destructor in use supplemented with a coal-fired boiler; the second week with the destructor off, the coal boiler alone being used; and the third week with the destructor in use again. As all the boilers feed into one common pipe range, it is not possible to run the destructor straight on to one steam dynamo, and meter the output in that manner. The object of this test was to find the ratio between the fuel value of refuse and the steam coal in use, and as the generating plant was the same during the whole of the time, the figures given below are reliable, in that they are obtained under ordinary conditions, without special preparations for a test.

Taking the five days, Sept. 21 to 25 inclusive, the units generated were 12,961, and 41 35 tons of coal were used. This gives an average of 313 units generated per ton of coal used and 7·1lb. of coal per unit. At an average price of 7s. per ton of coal delivered, this equals ·266d. per unit generated. If we take the figures from Sept. 14 to 20 and Sept. 26 to Oct. 2, each inclusive, we find that 36,196 units were generated for the destruction of 265,075 tons of refuse with the aid of 73·8 tons of coal. Taking a basis of 313 units per ton of coal, 23,100 units were generated by coal, leaving 13,096 units generated by refuse, being an average of 49·8 units per ton of refuse. No doubt these figures are well above the average for a destructor, but the exceptionally good daily load factor assists materially to produce this result.

During the 12 months ended March, 1903, 6,525 tons of refuse were destroyed, the six stokers' wages amounted to £486. 13s. 8d, including labour in stoking 1,502 tons 7cwt. of coal. This is equal to a cost for labour alone of 1s. 5·89d. per ton of refuse, and includes all cleaning of boilers,

* Abstract of paper read before the Leeds Local Section of the Institution of Electrical Engineers.

flues, economisers, etc. Without a destructor two stokers would be required for coal firing, and, on the other hand, at least five men are required for the furnaces. If 4½ men are taken for the furnaces and 1½ for the coal boilers, the cost of labour will be 1s. 1½d. per ton of refuse destroyed. Thus, for an expenditure of 1s. 1½d. we get 49·8 units from each ton of refuse, which, if generated from coal, with the same plant and all other conditions equal, would have cost 1s. 1d. (49·8 × ·266), so that as far as an electricity department is concerned, is at least no gain, but a slight loss.

Where, then, is the pecuniary advantage of a destructor plant? It has been previously stated that sanitation must be the aim of a destructor station. Tipping, barging away to sea are obsolete methods of disposing of refuse. The only sanitary method is complete destruction by fire. This being granted, then municipal authorities are justified in seeking to obtain a remunerative outlet for the power that may be produced in the destruction of refuse. The figures of the tests already referred to, made during September, 1903, at Shipley, are better than those which would be obtained over a whole year's working, but the writer is of opinion that it would be perfectly safe to assume that 40 units per ton of refuse would be the figure for the year ending March, 1904; 6,000 tons of refuse will then give 240,000 units, and at a cost of ·266d. for fuel per unit generated will reduce the coal bill by £270, as a set-off against £332. 10s. (6,000 × 1/1½), the cost of destroying the refuse under the most favourable conditions. To the town, then, this is a clear gain of £270, as destruction by fire is the only possible way, and this is the saving if arrangements are made to utilise the power obtained from destruction.

But to an electricity department this steam is not worth the £270 mentioned; against that must be set the unreliability of the refuse, the quality and quantity varying from day to day; the supervision to be given to a destructor steam-raising plant as compared with a coal steam-raising plant is far more, and necessitates a larger staff. It is impossible to keep out of the engine-room all the dust incidental to works of this description, and these and other disadvantages reduce the pecuniary value of the steam thus generated. From the Health Committee standpoint, the reduction of management expenses, and the fact that a skilled staff at the electricity station is available for repairs and attention to the destructor plant, are obvious advantages.

The day load of a central station—that is, traction, motor load, battery charging, etc.—provides a remunerative outlet for the power generated, enabling the refuse to be dealt with as delivered. The results given above show that it is possible for a council to combine the two undertakings, but the advantage to the electricity department is questionable. No engineer would prefer a destructor if he could turn his generators without one. The calorific value of the refuse varies almost directly as the price of coal in that district; if the coal is cheap, the refuse is good, and if coal is costly, the refuse is of less value. The figures given in Table A show that, with the best results, it it is more expensive to generate from a destructor than from coal, and so we cannot look to a destructor to be a certain factor in economical generation of electricity.

(To be continued.)

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

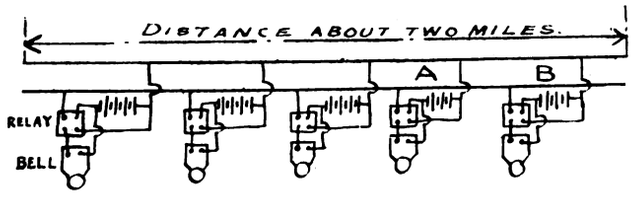
QUESTIONS.

639. A 60-h.p. direct-coupled motor, shunt-wound for a speed of 280 revolutions per minute, is to be started up so that it runs very slowly for only a few seconds and then stops dead. This is required for the purpose of setting the machine. It really only has to just move round and then stop in the exact position that is wanted on the machine.—E. B. C.

640. Explain fully what is the use of the copper earth sheath as used on three-phase cables, and why the lead sheath is not used.—C. W. G.

ANSWERS.

631. The diagram shows an underground signalling circuit with five bells in parallel. The line wires are galvanised iron wires on porcelain insulators. By putting together the two wires anywhere all five bells ring, which is necessary. It is desired to fix a telephone (wall pattern) at stations A and B, and to have a portable (watch pattern) to speak from any part of the line. Can this be



done with the present wires by placing switches at A and B, or, if not, what would be the best and cheapest means of getting the required communication?

Best Answer to No. 631 (*awarded* 10*s.*).—"Pitman" asks in his question whether it be possible to connect two telephones, respectively at stations A and B, so that anyone at, say, X can communicate with either A or B along the present two wires. This is possible under certain conditions, and in Fig. 1 will be found a diagram of all the

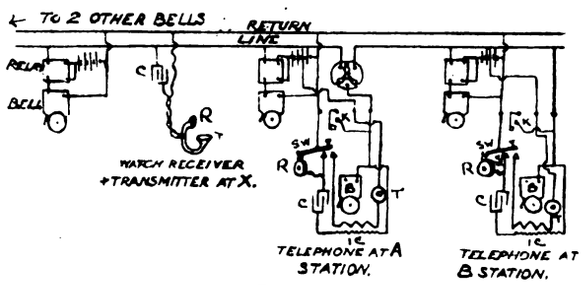


FIG. 1.

necessary connections to accomplish this end. On studying the above connections on the telephones, it will be noticed that there are a few varieties to the ordinary methods of connections on the instruments themselves. These are on account of the two line wires being used for the bells as well, as on this account it will be noticed that these are both always live owing to the bell batteries at all five stations. In Fig. 1, R is the receiver; T is the transmitter; I C is the induction coil; B is the bell; K is the key for ringing up other stations; C is a small capacity; S W is the switch hook on which the receiver hangs; S is the spring to pull S W down when R is off it

Owing to the fact that space is limited for showing the connections clearly on the telephone instruments, below will be found Fig. 2, which gives the ordinary method of connecting one, so that we can then compare these two figures and account for the differences. On comparing these two, it will be at once noticed that (*a*) the bell is not connected up in Fig. 1; (*b*) there is no connection to the carbon of the battery on terminal C in Fig. 1; (*c*) there is a condenser in series with the receiver in Fig. 1 and not in Fig. 2.

The reasons for these are as follows: (*a*) If the bell were to be connected up in Fig. 1 it would ring always, as there would be a complete circuit from any of the five batteries through its relay along the return line wire to the Z E terminal on the telephones, thence to the switch hook arm which is hard against the bell contact, and so through the bell and back again *viâ* the line wire. Of course, it would never do to have a circuit like this, as the batteries would all very soon get run down, so this connection to the bell has to be cut out. (*b*) The connection on to the terminal of the instrument from the carbon of the battery is simply used in the key circuit to ring up another instrument. As, however, above I have just shown

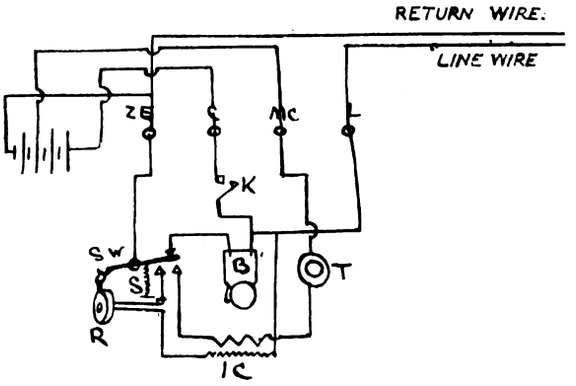

FIG. 2.

it is impossible to use the bells of the instruments, this connection becomes quite unnecessary. (*c*) With reference to the condensers, it will readily be seen that if there were none, and the receiver be taken off the hook, when the arm has sprung back, making the other two contacts below, there is a circuit now through the bell batteries, relay, line return, receiver, induction coil, etc., in instrument back to the battery, which would completely interfere with any conversation which might be going on along the line. Inserting the condenser in series with the receiver stops all these continuous currents, but does not affect any alternating currents due to speech which apparently pass through it.

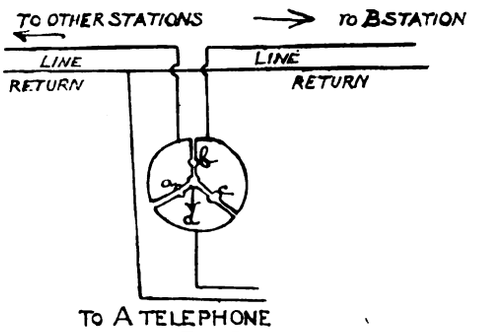

FIG. 3.

There must also be a three-way plug switch (Fig. 3) at A, so as to be able to cut B out if X is speaking to A, and *vice versâ*, and also to allow A to speak to B. It must be remembered, however, when any conversation is finished to replace the plug in the central position, otherwise station B is entirely cut off for bells and all.

Procedure is now as follows: When X requires to speak to either A or B he must first bring the two bare line wires together, thus ringing bells at all five stations. To indicate that this is not an ordinary bell signal, he must give a certain number of rings in succession. X now connects his portable instrument on to the two bare wires and listens till A answers, when he expresses his wishes. A must first shift the plug in the switch to the *a* position, so as to cut B's instrument out, as otherwise A and B would be in parallel, and probably neither understand. Now, if

Digitized by Google

X requires to communicate with B, A must put plug in *b* position so as to cut himself out of circuit. After the conversation is over a certain "ring off" signal must be given, which rings on all five bells, and then A must shift the plug to the *d* position. Position *c* is obviously for use when A and B are conversing. Speech on these two lines may be fairly satisfactory, but it will be seen that much depends on the switching at A station; also all the alternating currents corresponding to the sound waves have to go through two condensers in series, and so the whole system, I am afraid would be rather poor; but it is the only method which can be adopted if only the present two bell line wires are to be used.

I should, however, strongly advise "Pitman" to instal either of the two following methods: Firstly, it will be necessary to run another bare wire the whole distance on insulators like the present two wires, one of which will be used together with the new one. This method, it will be found, entirely does away with the necessity of using condensers in the receiver circuits, and so will be found to be much more satisfactory; also X can ring up direct on the telephones, and so does not interfere with the other bell stations. Fig. 4 gives a diagram of the necessary connections, where C and D are the present bell wires, and E is the additional line wire for the telephones, and C is used as the return wire. As in the former case, it will be found necessary to have a three-way plug switch at the A station, and with the use of this it is possible for A to call up B direct, but it will depend on the position of the plug as to whether B will be able to call A direct, but, of course, if not, he can call A by a signal of all the five bells, when, on shifting plug to C position, connection is made through.

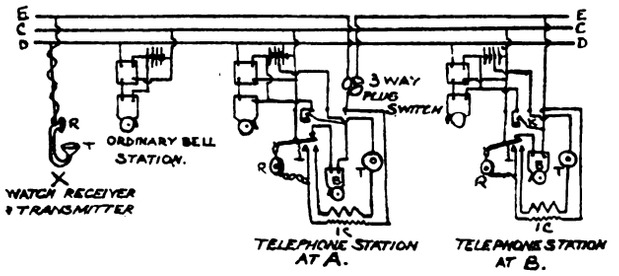

FIG. 4.

In passing, it might be as well to draw attention, when connecting on the telephone to the battery, in all cases to make the connection from the zinc direct on to a wire which will be the return wire, and to connect the Z E terminal on the telephone to this. Otherwise it will be seen that the relay of that particular bell will be short-circuited, and so that bell could never ring.

Procedure is now as follows: When X requires to call up a station he must bring the two bell lines, C and D, together as before, and so ring all five bells, unless he carries a small pocket accumulator, or two or three dry cells, in which case, if he connects these across the two lines C and E, he rings up direct on the telephone instruments, which is obviously the better method. After this, procedure is the same as in the first method as to switching, etc., at the three-way plug switch.

My last method is, in my estimation, the best of the three, but necessitates still another wire being run, making four in all, C, D, E, and F. The necessary connections are shown in Fig. 5, and it will now be seen that stations A and B each have a separate line wire, whilst using the common return, C, as before In this it will be seen that each station, A and B, has a separate line to itself, so that X simply has to hook his portable on to the line of the station he wishes to call up and on to the common return wire, C. This entirely does away with the three-way plug switch at A, and its attendant trouble as to where the plug is, which occurred in the last two cases. Now, if A requires to call up B, or *vice versâ*, as each has a separate line, it becomes necessary for him to switch his instrument on to the other's line, which is accomplished by means of the single-way plug switches at P. At ordinary times, however, except when in use, it will be necessary for both plugs to be out, as otherwise both telephone stations would be in parallel. When X calls he will connect his battery across the line wire of the station required and the return, and so ring, unless he ring up all five bell stations, when he will remove the battery and substitute his portable telephone. This last method I should recommend "Pitman" to adopt, on account of its greater simplicity and therefore reliability, and he will find that the only extra cost above method 2 is for the extra line and necessary insulators, which will be amply repaid by the better working. If this method be more costly than is required he had better adopt the second system, which is far and away better than my first, which, personally, though I think it might work, I should not be at all keen on adopting.

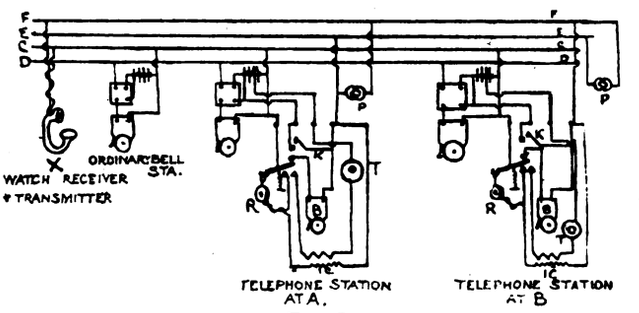

FIG. 5.

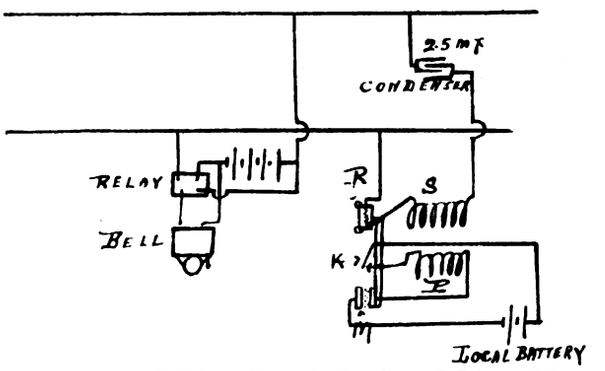
I have been wondering if an earth-return system could be devised, but it will be seen that there becomes trouble in earthing one terminal of the portable telephone, and the only way I see of getting over this is to use one of the existing bell wires earthed, and in this case the method becomes identical with the first given in Fig. 1. I feel perfectly confident that if "Pitman" adopts my third method, wherein each station has a separate line wire, he will have a very satisfactory and efficient telephone system down his mine, and might just as well conclude by saying that if there are at present any other electric wires, either for traction or light, down the pit running anywhere near the bell wires, it would be as well to cross any extra wires he may run and the bell wires once or more in the parts affected, so as to overcome any inductive effects which might possibly occur.—E. R. ALEXANDER.

Answer to No. 631 (*awarded* 5*s.*).—The simplest method of fulfilling the requirements of "Pitman" is to bridge the main circuit at point A or B (or, in fact, any other point) with a telephone instrument consisting of a "Handcom" combination receiver and transmitter, together with an ordinary telephone induction coil, in the secondary of which a condenser is inserted having a capacity of about 2·5 microfarads, as shown in diagram herewith. The



R, Receiver; K, Primary Key; M, Microphone; P, Primary Coil; S, Secondary Coil.

portable set must also have a condenser fitted, the function of which is to prevent the "ringing" circuit being completed whilst telephones are being used, but at the same time it offers no impediment to "speech" currents, which are of an alternating nature. Ringing is done in the usual manner, as described by enquirer, and any station called by a prearranged code of rings.—A. R. P.

Answer to No. 631 (*awarded* 5*s.*).—The best and cheapest means of fixing telephones between stations A and B would be to make C the line for the telephones, and bring the

Digitized by Google

telephone return to earth. To make C line wire we would still keep the bells on metallic circuit, thus allowing them no earth connection. It would not answer for the telephones to have A to earth. The bells could thus be put into circuit without their return flowing through and ringing the telephones. Care must be taken that all the three wires, A, B, and C, are free from earth, because if either of them got to earth great trouble would be caused to the telephones, and if A and C got earthed together it would make a complete circuit and run the cells down. Of course, the watch pattern telephone would only be connected when required for use. When it was disconnected,

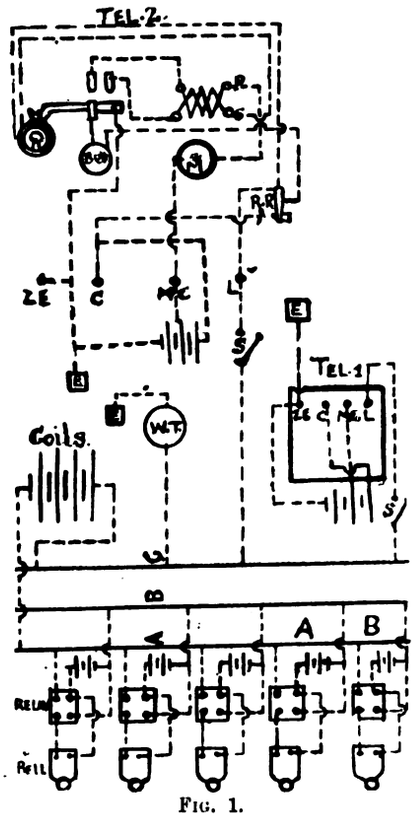


FIG. 1.

the two wall telephones would answer all right, but when the watch telephone was put into circuit it would ring telephones at A and B station, and neither would know which was required. The way I would suggest to get over this difficulty is, as is done in many pits, have certain rings for telephones—say, from telephone 1, to ring up telephone 2, one short ring; and from telephone 2, to ring up telephone 1, one short ring: then, when watch telephone was used, to give one loud ring for telephone 1 and two loud rings for telephone 2. By this method the difficulty could easily be got over, the only fault being that all the time conversation was going on between the watch telephone and one of the wall telephones, the other wall telephone bell would be constantly ringing. This can be got over by fixing switches at each wall telephone, as in Fig. 1, so that the telephone that is not in use could be switched off till conversation was finished, and then put the switch back so that communication can again be made between the two wall telephones.—J. P. S., SUNDERLAND.

Question No. 632.—Is there any advantage in compounding a motor which is needed to be started up quickly on full load very frequently? The idea is that it can be started up as a series machine, the shunt being thrown in afterwards. The motor would be of 8 h.p., and work at 550 volts.

Best Answer to No. 632 (*awarded* 10*s.*).—The advantages of using a compound-wound motor for handling intermittent and heavy loads are considerable, provided, of course, that *both* windings are made use of at starting, and that the windings are connected up "cumulatively." It may be pointed out that compound-wound motors are of two classes. In one case the series winding opposes the shunt winding, with the object of compensating for fall in speed with load, or for obtaining speeds increasing with the load. Such motors are rarely required at the present day, for the same result can be obtained with a plain shunt motor of good design by setting the brushes with such a forward lead as to maintain a constant speed through the influence of armature reaction. The other case of compound winding, and the one that is of much more use, is that with the series coil *helping* the shunt. A motor connected up in such a manner is called "cumulatively compounded," while "differentially compounded" is used to signify the previously mentioned connections. Manufacturers have accepted the former method of connections as standard for compound-wound motors, the latter arrangement being only supplied unless specially requested.

The writer does not recommend the arrangement mentioned in the question for starting up. At starting up, especially on heavy loads, the maximum possible torque is required if the moter is to start up quickly. This result can be obtained by making use of both shunt and series windings. The curves of Fig. 1 bring out this point very strongly. The two sets of curves show the performance of a shunt and a compound wound motor with respect to running current, torque, and speed. The abscissæ are torques expressed in percentage of full-load running torques, and the heavy line at 100 per cent. represents normal full load for both motors. The ordinates are current, efficiency, and speed, also expressed in percentages for comparison. The curves were obtained from actual tests on modern commercial motors, the shunt motor having a rating of 5 h.p., 230 volts, 950 revolutions per minute, and the compound motor having a rating of 5 h.p., 230 volts, 1,025 revolutions per minute. The speed and current tests were made by applying a Prony brake to the motor running free and gradually tightening it until the motor stopped. The efficiency curve is the same for both motors up to 150 per cent. of full load torque. The speed curves, which originate in the upper left-hand corner, show that at full load the shunt motor falls off about 4 per cent, and the compound motor about 7½ per cent. The shunt motor stops when the torque reaches 6·4 times the normal torque, and the compound motor stops at 10·8 times normal torque. This is a very important point, and clearly shows the advantage of a compound motor for starting up against heavy loads. It will also be seen from the current curves that the current consumption of the compound motor is materially less at heavy loads than that for the shunt motor. The starting torque of the compound motor is 70 per cent. greater than that of the shunt motor, while the starting current is less than that of the shunt motor when starting up. The curves serve also to illustrate the disadvantage and impracticability of starting up a compound motor on a heavy load by means of the series coil only. The torque developed in this case will be practically the starting torque of the compound motor minus the starting torque of the shunt motor (see Fig. 1), and this works out at about 40 per cent. of the starting torque when both shunt and series coils are used. It will also be clear that the starting current will be higher when the series coil only is used than that when both sets of windings are made use of. The extra complication of the switchgear also makes the method suggested unpractical.

Besides the great advantage of the compound motor enumerated in the above discussion—viz., the facility with which it can start against heavy loads in comparison with the shunt motor—there are other advantages attending the use of the compound-wound motor. In a compound-wound motor with the windings connected up cumulatively, the speed obviously decreases with increasing load, and the extent of the decrease is dependent on the relative strengths of shunt and series fields. The full-load speed of compound motors varies, in practice, from about 7 per cent. to 15 per cent. of the no-load speed. Much more extreme proportions may be used, and this is very desirable in the case of motors required to handle intermittent and very heavy loads, where there is no objection to the heaviest work being performed at much slower speeds. This is of great advantage to the whole supply system; the generating plant is more evenly loaded and the pressure regulation is better. Moreover, it is a considerable advantage as regards good commutation that a motor should carry its heaviest loads at reduced speeds. This is because the frequency of commutation, and therefore the reactance voltage, for a given current is proportional to the speed. The compound-

Digitized by Google

wound motor has, in this respect, to a certain extent, the advantage obtained in a series motor—viz., less tendency to spark with increasing load. A shunt motor does not possess this property; in fact, a shunt motor has a greater tendency to spark on overloads, and to overcome this the reactance voltage should be low.

The chief point wherein calculations relating to a compound-wound motor differ from those of a shunt motor, relates to its speed at various loads. The estimation of a compound motor's speed may be illustrated by the case of a 30-b.p. 500-volt motor. It has a shunt winding giving a constant magnetomotive force of 3,000 ampere-turns per spool. When developing 30 h.p. the motor consumes a

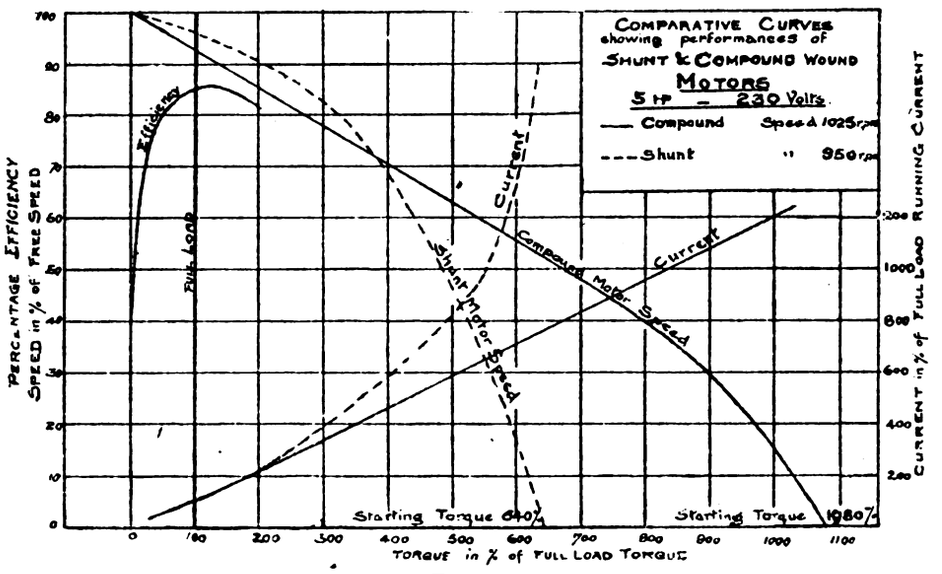

FIG. 1.

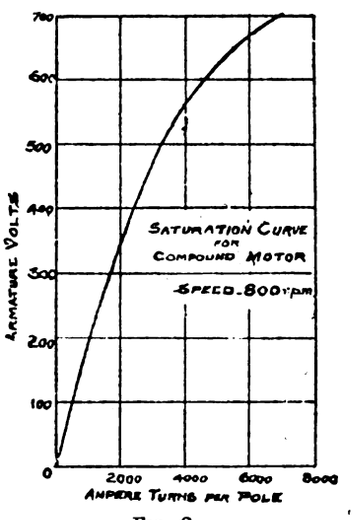

FIG. 2.

current of 50 amperes, which pass through a series winding with 50 turns per pole. Therefore, the series excitation at full load is 50 × 50 = 2,500 ampere-turns per pole. The saturation curve of the machine at its no-load speed of 800 revolutions per minute is given in Fig. 2. From the saturation curve the speeds for various loads and 500 terminal volts may be calculated, as indicated in the following table:

CHARACTERISTICS OF 30-H.P. COMPOUND-WOUND MOTOR AT VARIOUS LOADS.

—	Per cent. of full load.					
	0	25	50	75	100	125
Amperes input	4	15	26	38	50	63
Series excitation per pole	200	750	1,300	1,900	2,500	3,150
Shunt " "	3,000	3,000	3 000	3,000	3,000	3,000
Total " "	3,200	3,750	4,300	4,900	5,500	6,150
Voltage for 800 r.p.m. (from saturation curve)	500	550	585	620	650	680
Speed for 500 volts (r.p.m.)	800	727	682	645	615	588

In this illustration it is convenient to assume—for the sake of simplicity—that the brushes are so placed that armature reaction compensates for the C R drop.

It may be mentioned that compound-wound motors are finding a wide application for special purposes, such as for mining plants and rolling mills. In one instance a large steel-wire rolling mill in Sweden is driven by a 400-h.p. 500-volt compound motor. This machine has two commutators, which are connected in series for low and parallel for high speeds. A wide speed regulation is also obtained by shunt regulation. The practical operation of this motor has been very satisfactory, and an abrupt variation of the load, from 100 h.p. to 600 h.p., can be safely stood without sparking and with fixed brush position.—A. D.

Answer to No. 632 (*awarded* 7*s.* 6*d.*).—The starting power of a compound-wound motor is always greater than that of the same motor with a plain shunt winding, because, with the former, the effect of armature reaction in reducing the torque is partially or wholly avoided.

When a shunt motor is switched into circuit by means of an ordinary starting switch, the action is somewhat as follows: (1) the shunt winding alone is connected to the supply mains, and the shunt current and magnetic flux gradually increase to their full values, the time taken for this depending on the self-induction of the shunt circuit and the eddy currents set up in the magnet iron by the change in flux; (2) the armature is switched into circuit in series with the whole starting resistance, and a certain small current passes, producing a torque which is proportional to the product of armature current and magnetic flux; (3) the starting resistance is gradually cut out, and the armature current increases until the normal full-load value is reached, when if sufficient time has elapsed to permit the flux to reach its full value, as described in (1), the full-load torque will be developed and the motor will start; (4) as the motor speed and the back voltage increase more of the starting resistance is cut out so as to maintain the armature current at its normal value, until, finally, all the resistance is cut out and the motor runs at full speed.

If during this process the starting resistance is cut out too quickly, bad results may be expected from two causes. Firstly, if the full-load current is reached before the full flux is attained, the motor will not start until an excess armature current is supplied, and the field-weakening effect of the armature reaction due to this excess current may lead to an actual reduction instead of an increase in the torque. This is shown in Fig. 1, which represents the

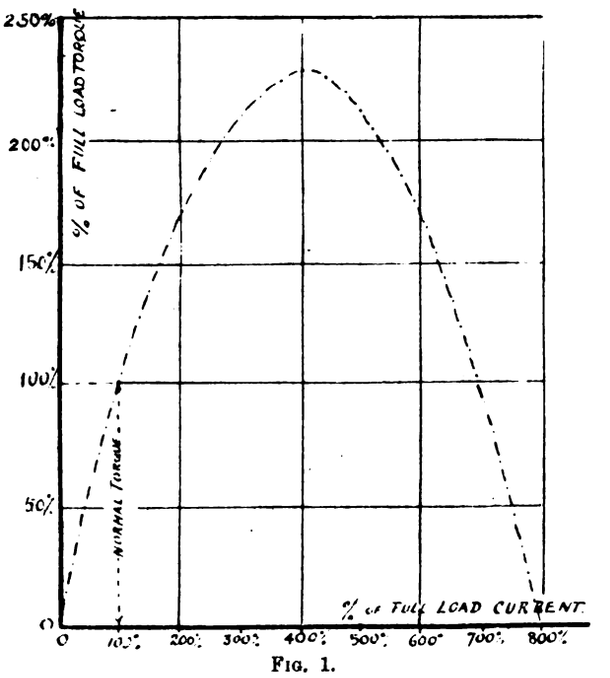

FIG. 1.

torque current curve of an ordinary shunt motor, in which the armature back ampere-turns at normal full load have

Digitized by Google

been assumed to equal one-eighth of the total field ampere-turns—a not unusual proportion. It will be seen that, even with the shunt fully excited, the maximum possible torque is slightly over twice the normal, whilst with the shunt only partially excited, or with a motor having a greater ratio of armature back ampere-turns to field ampere-turns, this maximum torque would be proportionately lower and would be reached at a correspondingly lower current. The second cause of trouble is the fact that, even if the full flux has been attained before the armature current reaches its normal value, the inertia of the armature and machinery driven by it may cause an excessive current to pass if the switch is moved too quickly. This would lead to the same result as above—viz, the reduction rather than increase of the torque with increasing armature current

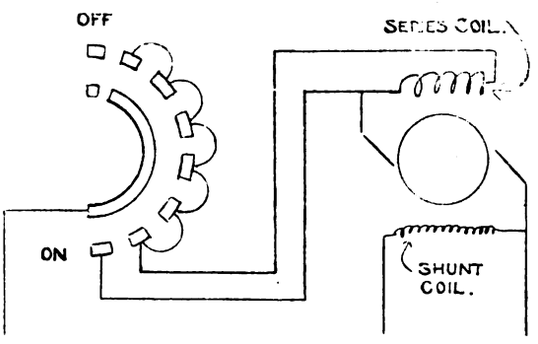
Trouble from both these causes can be avoided by the employment of a compound winding. For then, if the amount of series winding is chosen to neutralise or more than neutralise the effect of armature reaction, it is clear that no sudden increase of armature current, however great, will be able to affect the flux. Consequently there is no longer any chance of the torque diminishing with increasing current. The self-induction of the series winding will, of course, be very much less than that of the shunt winding owing to the lower number of turns in the former, and it would, therefore, seem advantageous to disconnect the shunt until after the full armature current is reached, so as to avoid the retarding effect of the closed shunt winding on the flux produced by the series winding. In practice, however, especially with small motors, the retardation of the flux due to self-induction and eddy currents is small compared with the time taken for the machine to attain full speed so that certainly no harm, and probably some good, would be done by leaving the shunt winding connected throughout.—Q.

Answer to No. 632 (*awarded* 5*s.*).—When any particular continuous-current motor is supplied with electrical current, the torque exerted upon its shaft in any condition of the motor, whether running or stationary, is proportional to the product of the flux per pole passing through the armature and the current flowing in the armature circuits. Hence, if in a shunt-wound motor we put on the normal field, and then pass the normal full-load current through the armature when stationary, we shall get full-load torque exerted, but no more, and as a motor which must start against what is colloquially termed "full load" has to start against a torque equal to that met at full load, it is easy to see that the torque exerted by the armature at starting and while running up to speed must be *more* than that when running at full load, since the motor must supply not only the normal torque to turn the shafting or lift the load, as the case may be, but must supply, in addition, the torque necessary to speedily accelerate the motor and its load up to full speed. An ordinary shunt motor can only give increase of torque by a proportionate increase of armature current, since its field, placed directly across the supply mains, cannot have its current raised. Hence, in starting a shunt motor against "full load," an excessive rush of current is bound to be taken; and if, as in cranes and lifts, the starting torque to be overcome is considerably greater than the running torque (owing to the friction of bearings being greater when standing than when in motion) the necessary current to start up and reach full speed quickly may be very great indeed. Here, then, is the advantage of supplying a compound-wound motor, for the poles being equipped with series coils for starting purposes, these give an additional number of ampere-turns on the poles, and by raising the flux give an increase of torque with normal current. And, again, if the current is allowed to rise above its full-load value, the torque will increase in a higher ratio than the current, since it is raised by the increase both of armature current and of field strength.

In the particular case cited, the motor of 8 h.p. at 550 volts will take a normal armature current of about 12 amperes. Its speed not being stated, one can only approximate at its dimensions, but being four polar it will probably have a normal flux of 1·5 megalines per pole, requiring, say, 4,500 ampere-turns. If, now, in addition to the shunt coils producing these, each pole has a series coil of 100 turns, there will be available (at normal armature current) an extra 1,200 ampere-turns per pole, making 5,700 in all, and raising the flux to about 1·7 megalines, giving, therefore, an increase of 13 per cent. in the starting torque when drawing, but normal full load current from the mains. The exact number of series turns must depend upon the requirements of the motor, and if very excessive starting torque is desirable it will be advisable to work the motor normally at some distance below the magnetic saturation point, so as to allow a big increase of flux when the series coils are in use. But it may be pointed out that as these coils will only be used at starting up—*i.e.*, for short periods at a time—it will be quite safe to work them at a much higher current density than can be allowed for the shunt coils, and hence the series coils will not occupy much space on the poles.

From the wording of the question, it appears that "G. H." considers there is something special in the flux produced by series coils, and that that excited by shunt coils is of no service in starting up, since we are told that "the idea is to start up as a series machine, and throw in the shunt afterwards." This is an utter fallacy, though by no means an uncommon one. The flux is just as useful whether produced by series or by shunt coils, and the sole advantages of series coils for starting (or, indeed, for running at any time) is that as pointed out above, with their use an increase of current causes the torque to increase in a greater ratio. But since we already have on the motor this shunt winding, we may avail ourselves of the ampere-turns this will give us, and use this advantage of the series coils to afford any extra ampere-turns that may be required. If the shunt coils are not to be used during starting, it will mean a very great increase in the amount of series copper to be put on the fields, and will certainly necessitate the use of a carcase a good deal too large intrinsically for this output, in order to afford room for all this copper.

If the speed at which the motor runs may vary considerably without harm, then one may use a compound motor, which would virtually be a series motor with shunt coils added to prevent racing. This would be used with both sets of coils permanently in use. If, on the other hand, a set running speed is required, then a shunt motor must be used normally—*i.e.*, the series coils must be cut



out when speed is reached—but special series coils will be added for use in starting in conjunction with the shunt coils. The annexed sketch shows the connections on the starting switch for this latter mode of operation. The arm of the switch would be furnished in the usual manner with a spring, so that the circuit can only be left "off" or "full on"—*i.e*, as shunt motor. If a maximum release is to be fitted, then the lead *to* the switch must be carried round the solenoid, since there are two leads thence to the motor, either of which may be overloaded. The shunt connection is not shown in the sketch. This would preferably be made by a subsidiary arm on the switch, and should be provided with a "kicking coil."—C. E. C.

Answer to No. 632 (*awarded* 5*s.*).—The object of compounding a motor which is started up with full load on is to obtain a large starting torque. In the case of elevators, hoists, etc., the power required to overcome the inertia of the moving parts at starting is very great, but after the motor has been running a few seconds the power required to keep the various parts moving falls off very considerably. The usual arrangement is to have, in addition to the shunt winding, a few series turns, just sufficient to

Digitized by Google

obtain the extra torque necessary at starting. This series winding is automatically cut out of circuit by the controller or starting switch some few seconds after starting, and the motor is left running as an ordinary shunt-wound machine.

The diagram (Fig. 1) shows the starting switch of a controller. The arm, A, moves slowly over the contacts, gradually cutting resistance out of the armature and series field. As soon as the arm reaches the contact marked C_1 half the series field is short-circuited, and when the arm reaches the contact C_2 the whole of the series winding is short-circuited, leaving the motor running with shunt field only. The foregoing arrangement is in use on several motors for working hoists, elevators, etc., to the writer's knowledge, and is found very satisfactory in practice. If the load on the motor after it has once been started is not of a very varying nature, "G. H." will find a shunt-wound

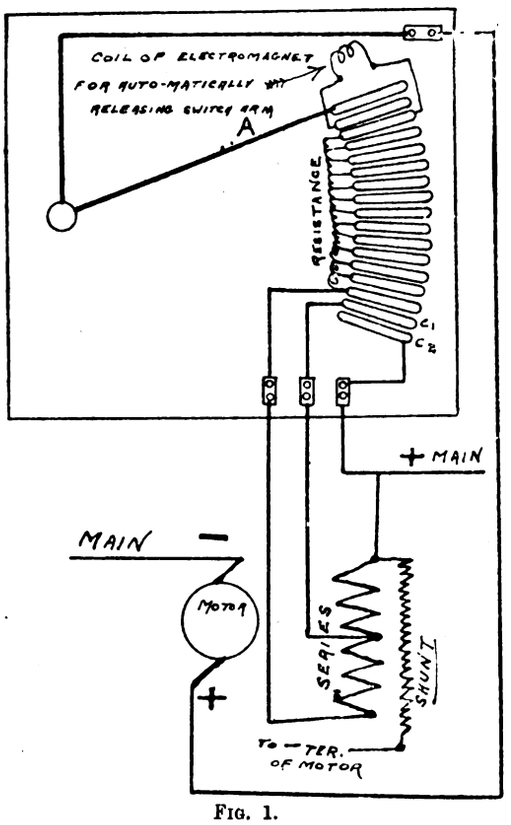


FIG. 1.

motor work quite satisfactorily, and run at practically constant speed.—C. V.

[N.B.—Will "C. V." kindly forward to us his name and address.—ED., *E. E.*]

PROVISIONAL ORDERS.

The following notices of intended application for provisional orders appear in the *Gazette*:

ELECTRIC LIGHT AND POWER.

Birkenhead Corporation, electric lighting extension; Lichfield City Council, electric lighting extension; Saffron Walden Corporation, electric lighting; Mansfield Woodhouse Urban District Council, electric lighting; Huddersfield Corporation, electric lighting extension to Golcar; Acton Urban District Council, electrical fitting and supply; Thornbury Rural District Council, electrical power and lighting; Gainsborough Urban District Council, electric lighting; Maldens and Coombe Urban District Council, electric lighting and power; Keynsham (Somerset) Electric Lighting and Power Company; Horley (Marshall Handyside Bennet, of the Chesnuts, Horley, and Robert Cornelius Quin, 13, Victoria-street, London). Watford Urban District Council, electric lighting: Newquay, Southern District Electricity Corporation, electric lighting; Ely, Southern District Electricity Corporation, electric light.

TRAMWAYS.

London United Tramways Company; Wardle Urban District Council; Leyton Urban District Council; Rotherham Corporation; Ossett Corporation; Bournemouth Corporation; Folkestone Corporation; Wallasey Urban District Council; Middlesbrough, Stockton-on-Tees, and Thornaby Imperial Tramways Company, Limited; Brighton Corporation; Wolverhampton Corporation; Altrincham Urban District Council; Harrow-road and Paddington Tramways Company; Hope and Castleton Light Railway Commissioners; West Metropolitan Railway Company; Chesterfield Corporation; Saddleworth and Springhead Tramways Company (abandonment of undertaking); West Ham Borough Council.

LEGAL INTELLIGENCE.

ELECTRICAL PUBLISHING COMPANY, LIMITED.

In the Chancery Division of the High Court of Justice on Tuesday, Mr. Justice Buckley, sitting for disposal of companies' business, had before him a petition to wind up the Electrical Publishing Company, Limited, the petitioner being Thomas Wm. Sheffield, of Trevellyan-buildings, Corporation-street, Manchester.

Mr. Astbury, K.C., for the petitioner, said the company was formed in July, 1902, for the purpose of carrying on the business of and publishing an electrical review, with offices in London. The nominal capital of the company was £14,500, of which £8,800 had been allotted. It was not quite correct to say they were all paid up; only part were paid up. The object was to carry out an agreement with one Theodore Feilden, who was to be the editor and publisher of this magazine. By the agreement of July, 1902, and referred to in the memorandum and articles of association, it was provided that the company should acquire the publications—meaning thereby the copyright of the title of the *Electrical Magazine* and other property and assets—from Feilden, who was appointed managing director and editor of the publication, in consideration of which the vendor was allotted 5,500 ordinary shares and 1,000 preference shares, and the remuneration for his services was to be £6 per week from the date of the registration of the company up to the date of publication, with travelling expenses in London at 10s. 6d. a day, and in the provinces at two guineas a day. What the petitioner complained of was that Feilden had nothing to sell. It turned out that there was no publication, and no preparation for publication. Mr. Feilden had been going on drawing money from the company, and great pressure had been brought to bear upon him. He now suggested that he might publish the magazine early next year, but nothing had been done at all, and petitioner alleged that the company was simply a company for putting a monthly or weekly sum into Mr. Feilden's pocket. The petitioner set forth that the company went to allotment in June, 1902, and at the date of the balance-sheet of June 30, 1903, 9,099 ordinary shares and 2,255 preference shares, including the vendor's, had been issued. Theodore Feilden had continued to draw his salary and expenses, and a sum of £1,350. 2s. 7d. had been expended on manager's salaries, directors' expenses, office furnishings, stationery, and other expenses at the date of the balance-sheet, leaving a balance in the bank at that date of £1,012. 17s. 7d. Between the months of March and September, 1902, there were circulated a large number of copies of the prospectus of the company, and many copies of the prospectus were distributed amongst electrical engineers, general engineers, and members of local authorities. The prospectus contained, among other statements, the following: "The maturation of Mr. Feilden's project has been the work of much careful thought. In the result Mr. Feilden has conceived and perfected a magazine entirely different to anything hitherto existing in this or any other country, rivalling the best productions of the United States, which are such enormous successes—in effect an international monthly record of things electrical, a compendium of information which should form an indispensable adjunct to every worker and thinker in the electrical science and progress, a journal presenting the mature thought of the pure scientist and authority in carefully selected signed articles, expert descriptions, fully illustrated, of the latest and best productions of the engineer and manufacturer of every country. Further technical details of the *Electrical Magazine* would be unpolitic to divulge, but leading authorities who are interested in the enterprise have declared that the publication is virtually unique in its comprehensiveness and utility." The petitioner upon the faith of the statements contained in the prospectus, which he believed to be true, applied for and was allotted 100 ordinary shares of £1 each, and had paid up £50 in respect of the shares and induced many of his friends to take shares in the company, and to promise to support the magazine with advertisements and subscriptions. The allotment took place in June, 1902, and the petitioner, relying upon the statements in the prospectus that the magazine had been perfected and approved by leading authorities, and that a profit was anticipated on the first year's working, expected the magazine to be published at once, and frequently urged Feilden to publish the magazine. In April, 1903, a paragraph appeared in the *Electrical Times* commenting unfavourably on the delay in the production of the magazine, and plainly insinuating that Mr. Feilden was working for his own interests and not for those of the shareholders. It was a very bitter paragraph. The petitioner called Feilden's attention to the article, and Feilden said he would take proceedings for libel against the writer of the article, but he had not done so. Up to the present time the magazine had not been published, nor, said counsel, was there any prospect of its ever being published. Feilden had produced a few dummy copies of the proposed magazine, which represented a week's work and a cost of 10s. per copy. Petitioner believed that if the whole of the remaining capital were subscribed, it would be totally inadequate to meet the expense of producing this magazine and maintaining it for 12 months until the advertisements began to pay; and Theodore Feilden, with his experience as a printer and of journalism, must have been fully aware of this at the time the company went to allotment. If the magazine were published, an outlay of from £400 to £500 per month would be required for 12 months to successfully establish the undertaking, and no return from the advertisements, on which the success of the magazine depended, could be expected during that period.

Digitized by Google

The amount available for calls upon shares was £2,404, and the number of shares remaining unallotted was 3,146, making a possible available capital of £5,550 to meet an estimated expenditure of £6,000 Owing to the delay in the publication of the magazine, many firms who had promised petitioner to advertise in the magazine had withdrawn their support. The dissatisfaction of the shareholders with the conduct of the undertaking was so great, and the undertaking had been so unfavourably criticised in the Press and among electrical people, that it was unlikely that any more shares would be taken up by the public. The only asset of the company was the bare copyright in the name, the office furniture, the cash now remaining in the bank, and a few contracts for advertisements, which were liable to be cancelled on the ground of the long delay in the publication of the magazine. Concluding, counsel submitted that the company was being called on solely in the interests of Feilden, and petitioner asked that it should be wound up.

Replying to questions by his Lordship. **Mr. Astbury** said his client held 100 shares, and he was supported by 27 shareholders holding 541 shares. The total number of shareholders was 154.

Mr. Hart, who opposed the petition, said he appeared for 58 shareholders holding 3,613 shares paid for in cash.

Mr. Astbury: My client states that they only hold 2,000 odd shares. I am told they have not given notice.

Mr. Hart said practically all had given notice.

Mr. Buckmaster, K.C., who appeared for the company, said further notices had been received that morning representing 160 shares. The petitioner had circularised shareholders and had received no more support than that stated.

Mr. Astbury said the opposing shareholders seemed also to have sent out circulars.

His Lordship: Assuming Mr. Feilden was to blame in every respect—I don't say he is for a moment—but let us discuss the matter on the footing that he has got 6,500 shares. If a meeting were held of shareholders and a vote taken on the question of whether there should be a voluntary winding-up, of course, he would be defeated.

Mr. Astbury: It would be hopeless.

His Lordship: You are a small minority of the shareholders, and the majority want the thing to go on. How can I, therefore, wind it up?

Mr Astbury: That is the difficulty. If I went into a lot of details I could show a good many things about this company which are unsatisfactory. As your Lordship takes the view expressed, I don't think I should waste the time of the Court.

His Lordship: I dismiss the petition with costs.

Mr. Buckmaster, K.C.: It may please my friend to know that the first number is ready for him.

WORKMEN'S COMPENSATION.

The case of Joseph Dixon *v.* the Darlington Corporation and J. G. White and Co., brought under the Workmen's Compensation Act, came before Judge Templer at Darlington County Court. Dixon was, it seems, employed by Mr. Peter Wilkinson, a sub-contractor for Messrs. White and Co., contractors for the new Corporation tramways. Owing to a horse taking fright in Parkgate he received personal injuries.

Mr. G. H. Watson, who appeared for Dixon, said Messrs. J. G. White had agreed to pay the injured man 12s. a week, and he asked for an order accordingly.

The **Town Clerk,** representing the Corporation, said his contention was that the Corporation were not liable, and he asked that they should not appear on the records.

Mr. Priestley, for Mr. Peter Wilkinson, against whom Messrs. White and Co. claimed indemnity, said he was prepared to go into the question of liability.

The Corporation was withdrawn.

The **Judge** said he would without prejudice make the award against White and Co., allowing costs on scale B.

The question of indemnity as between Messrs. White and Co. and Mr. P. Wilkinson was arranged to be heard later.

POST OFFICE TELEPHONES.

His Honour Judge Russell held a special sitting at the Kingston-on-Thames County Court on Friday to hear an action, by way of an application by the Postmaster-General to compel the Urban District Council of Wimbledon to consent to the erection of telephone poles and wires in certain parts of the urban district.

Sir Robert Hunter, for the Postmaster-General, explained that the Post Office sought the authority of the Court for the construction of three small lines of telephone wires and posts in Gap-road, Haydon's-road, Beulah-road, Dundonald-road, and Garfield-road, and the action arose under the Telegraph Acts of 1863 and 1878, which gave the Postmaster-General power to place telegraphs or telephones in, under, on, over, along, or across any public road, and to erect posts thereon for the purpose, subject to the consent of the local authority, and if the local authority withheld consent, then the matter was to be referred for decision to a county court judge. Application for consent was made to the Wimbledon District Council on Aug. 27, 1903. The Council refused, unless the lines were laid underground in Gap-road and Haydon's-road and ornamental iron poles were erected in the other roads. This the Postmaster-General was unable to consent to, on the ground of the great expense that would be entailed. If they were to be compelled to lay the lines underground and to erect ornamental iron poles it would be impossible, having regard to the rates charged to the public, to provide the system which Parliament expected and the public required.

Evidence having been heard,

His Honour, in giving his decision, said that, having regard to the appearance of Gap-road and Haydon's-road, he did not think the erection of iron poles would very much interfere with it, and the proposal of the Postmaster-General to erect iron poles there instead of laying underground wires he considered a proper one. As to the other roads, judging from the photographs before him, he did not think that painted wooden poles would interfere with the æsthetic character of the neighbourhood, so he thought the proposal of the Post Office was a fair one. He refused to allow costs.

COMPANIES' MEETINGS AND REPORTS.

GENEVA TRAMWAYS.

The report of the directors for the period from the incorporation of the Company to Sept. 30 last states that the Company was registered on Dec. 6, 1901, for the purpose of acquiring shares of the Compagnie Genevoise des Tramways Electriques, a company incorporated under the laws of the Swiss Republic, and owning and working a complete system of tramways about 136 km. in extent in and about the city and canton of Geneva. Solely dependent as it is for its revenue upon the profits of the Swiss company, this Company has become financially involved. In the belief that the suspension of profit-earning by the Swiss company was occasioned by temporary causes only, the directors obtained from Messrs. L. Hirsch and Co. loans amounting to £38,250, with which to meet the interest on the debentures falling due on July 1, 1902, and Jan. 1, 1903, but when it became apparent that a protracted period must elapse before the Swiss company could earn sufficient profit to provide this Company's debenture interest, and that further funds would possibly be required for the purposes of the Swiss company and of this Company, the directors were compelled to propose to the debenture holders a rearrangement of the finances of the Company. At a meeting of the debenture holders held on June 25, 1903, it was resolved to postpone for three years from Jan. 1, 1903, the payment of interest on the 4½ per cent. debentures, and to authorise the Company to create £20,000 of 5 per cent. short term prior lien debentures charged upon the shares held in the Swiss company, and to issue £39,692 5 per cent. third debentures in satisfaction of the previous advances of Messrs. L. Hirsch and Co. Neither the prior lien nor the third debentures have yet been issued.

NEW COMPANIES REGISTERED.

T. H. Wathes and Co., Limited.—Capital, £3,000. Objects: to adopt and take over and carry on the business of T. H. Wathes as an electric power, light, and telephone engineer at 13, Belgrave-gate, Leicester, etc.

Western Electric Distributing Corporation, Limited.—Capital, £10,000. Objects: to adopt an agreement with the Bristol Trust, Limited, and to carry on the business of suppliers of electric light and power, electricians, electrical engineers, etc.

Werner Freres, Limited.—Capital, £120,000. Objects: to take over and carry on the business of Werner Freres at 10bis, Avenue de la Grande Armee, Paris, and Rue Grefhulle, Levallois-Peret (Seine), France, for the sale of motors, motor-cycles, motorcars, cycles, vehicles, batteries, accumulators, cells, and the like, electricians, etc.

St. Albans and District Electric Supply Company, Limited (79,078).—Capital, £25,000. Objects: to carry on the business of suppliers of electricity, carriers of passengers and goods, electrical engineers, etc.

Power Plant Company, Limited (79,151).—Capital, £500. Object: to carry on the business of engineers, merchants, agents, contractors, builders, ironfounders, etc. Registered office: 20, New Bridge-street, E.C.

Manchester Carriage Company (1903), Limited.—Capital, £30,000. Object: to carry on the business of proprietors, manufacturers, repairers, and hirers of and dealers in omnibuses, motorcars, and other vehicles, whether propelled or drawn by manual, animal, electrical, or other power. Registered office: 6A, Wilmslow-road, Rusholme, Manchester.

Electrical Turnery, Limited.—Capital, £2,000. Object: to adopt an agreement between Electrical Turnery, Limited, and to carry on the business of turners, pattern-makers, founders, telegraph, telephone, electric, and general engineers, and dealers in electrical and other bells, telephones, lamps, and apparatus, etc.

British Accumulator Company, Limited (79,191).—Capital, £5,000. Object: to acquire and carry on the business of electric accumulator merchants carried on as the British Accumulator Company, at Parliament-mansions, Westminster.

Additional Traffic Returns.—Anglo-Argentine, £1,963 increase; Barcelona Ensanche y Gracia, £133 increase; Barcelona, £32 decrease; Brisbane, £90 decrease (month of August, £11,736, increase £294), British Columbia Electric (month of March), gross earnings £10,352, net income £2,659; Buenos Ayres and Belgrano Electric, £205 increase (month of October, £14,055, increase £1,002); Calcutta, £288 increase; Cape Town (month of October), receipts £16,229, expenditure £9,044; Isle of Thanet Electric, £29 increase; Lisbon Electric (month of October), receipts 93,725 milreis, expenses 50,350 milreis; Mexico Electric (month of August), receipts £48,600, expenses £27,900; Perth Electric, £266 increase; Port Elizabeth (month o October), receipts £3,972, expenditure £2,879.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Pontypridd.—The District Council invite tenders for the supply of six single and six double-deck electric cars.

Middlesbrough.—Tenders are required by the Corporation for dynamos, boilers, and condensers, by 28th inst.

Preston.—The Corporation invite tenders for a traction switchboard and accessories. Tenders by Dec. 12. See advertisement.

Maidstone.—The Corporation invite tenders for the construction and equipment of light railways. Tenders by Dec. 7. See advertisement in last issue.

Canosa di Puglia (Italy).—The Municipality will receive tenders for installing and working electric lighting for 50 years. Tenders by 30th inst.

Hornsey.—The District Council invite tenders for one 300-kw. steam dynamo to be delivered in October, 1904, and another in March, 1905.

Dudley.—The Guardians invite tenders for the supply and fixing of the various appliances for the electric installation to the laundry and boiler house.

Wood Green.—The Urban District Council invite tenders for the erection of a power station and the buildings in connection with the Council's electric lighting scheme.

Birmingham.—The Birmingham Tame and Rea District Drainage Board, 9, Bennett's-hill, Birmingham, invite tenders for three steel Lancashire boilers. Tenders by Dec. 8.

York.—The North-Eastern Railway Company invite tenders for telegraph apparatus, telegraph wire, and line stores. Forms of tender from Mr. C. H. Ellison, superintendent, York. Tenders by Dec. 7.

Batley.—The Town Council invite tenders for the erection of building for refuse destructor. Specifications, etc., may be obtained from the Borough Surveyor, Branch-road. Tenders by 30th inst.

Greenwich.—The London County Council invite tenders for six electrically-driven three-throw boiler feed pumps. Specifications, etc., at the County Hall, Spring-gardens, S.W. Tenders by Jan. 19.

Cape Town (South Africa).—The Directors of the Cape Town Industrial Exhibition (International) invite offers for lighting the grounds, etc. Tenders to Palmerston House, Old Broad-street, London, E.C.

Greenwich.—The London County Council invite tenders for the supply delivery, and erection of four 3,000-kw. generators with exciters. Tenders by 10 a.m. on Dec. 8. See advertisement in former issue.

Wisby (Sweden).—Tenders are invited for a private and public electricity supply estimated to cost 180,000 kroner. Particulars may be obtained from the Director of the Draetselkammaren at the above place.

King's Norton and Northfield.—The Council invite tenders for the erection of car-sheds and waiting room. Tenders by 30th inst. to Mr. Edwin Docker, clerk to the Council, 10, Newhall-street, Birmingham.

Sydney (N.S.W.).—Tenders are asked for the supply of continuous and alternating current meters. Specifications, conditions, and forms of tender are obtainable from Messrs. Preece and Cardew, 8, Queen Anne's-gate, S.W.

London, W.—The Great Western Railway Company invite tenders for the supply, delivery, and erection of water-tube boilers, engines, three-phase generators, and auxiliary plant at Park Royal, near Acton. Tenders by Dec. 7.

North-Eastern Railway.—The Directors invite tenders for arc lamp carbons and electric wires and cables, etc., for the first half of 1904. Specifications, etc., from Mr. E. H. Clark, Stores, Gateshead. Tenders by Dec. 7.

Burslem.—The Electric Lighting Committee invite tenders for the erection and completion of the generating station on a vacant site at the gasworks, Longport. Specifications, etc., from the Borough Electrical Engineer. Tenders by 30th inst.

London County Council Tramways.—The Council invite tenders for the wiring and fitting for electric lighting of five substations and three car-sheds in connection with the tramways. Tenders by Dec. 5. See advertisement in former issue.

Brighton.—The Council invite tenders for six water-tube boilers; a system of steam, exhaust, feed, blow-off, and suction pipes; and cast-iron storage tanks. Specifications, etc., may be obtained from Mr. Francis J. Tillstone, Town Hall, Brighton. Tenders by Dec. 7.

London, N.—The Hornsey Urban District Council invite tenders for the supply of meters, indicators, and consumers' fuse boxes. Specifications, etc., may be obtained from Mr. Norman Staniland, Electricity Works, Tottenham-lane, Hornsey. Tenders by 30th inst.

Christchurch (New Zealand).—Tenders are invited for the complete installation of electrical tramways, other than buildings. Specifications, etc., may be obtained from the Agent-General for New Zealand, Victoria-street, S.W. Tenders by March 17. See advertisement in last issue.

Dublin.—The United Tramways Company invite tenders for the supply of general stores, including car fittings, iron, steel, castings, oils, paints, glass, brushes, ironmongery, harness materials, electrical supplies, timber, etc., for year ending Dec. 31, 1904. Tenders by 30th inst.

Belfast.—The Committee invite tenders for the supply and erection of a complete heating and ventilating system, including steam boilers, heaters, etc., engines, blowers, and electric fans. Tenders by Dec. 4 to Messrs. Young and Mackenzie, architects, Scottish Amicable Buildings, Belfast.

Brussels.—Tenders are required for the electric lighting of the law courts. Specification, No. 111 (3½d.), and plans (4s. 9d.), may be obtained from 15, Rue de Augustine, Brussels. Tenders by registered letter to Direction générale des ponts et chaussées, 38, Rue de Louvain, Brussels, by Nov. 30.

Culiacan (Mexico).—Tenders are invited for lighting the town by electricity: 60 arc lamps of 1,200 c.p. and 110 incandescents of 50, 30, and 16 c.p. will be required. Propositions will be received by letter until Dec. 31 in the Secretaria del Ayuntamiento, Culiacan, where further information may be obtained.

West Ham.—The Education Committee invite tenders for the electric wiring and fittings and for the hot-water heating apparatus required at the Whalebone-lane Higher Elementary School, Stratford, E., and Shipman-road School, Custom House, E., now in course of erection. Tenders by Dec. 14. See advertisement in last issue.

Madrid.—The Government have issued an order granting an appropriation of 6,000 litres of water per second from the River Tea, in the municipal boundary of Mordariz, province of Pontevedra, for the production, by a fall of 6·40m., of electrical power for industrial uses, for which water power electric plant will be required.

Handforth (near Manchester).—The Guardians of Chorlton-upon-Medlock Union invite tenders for an electric motor for the new laundry at Styal Cottage Homes, Handforth, near Manchester. Specifications, etc., can be obtained from the consulting electrical engineer, Mr. G. R. Peers, A.M.I.E.E., 16, John Dalton-street, Manchester.

London, S.W.—The London County Council invite tenders for the supply and delivery of about 6,850 tons of steel girder tramway rails, fishplates, and bolts and nuts, and for 4,100 tons of steel slot rails, and 1,490 tons of steel conductor tee rails required for electric traction on the Council's tramways. Specifications, etc., from Engineers' Department, and tenders to the Clerk, County Hall, Spring-gardens, by Dec. 15.

Sydney (New South Wales).—Tenders will be received at the office of the Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 30, for the supply and delivery at the departmental stores, Sydney, of telegraph, telephone, and electric light material. Specifications, etc., may be seen and tender forms obtained at the General Post Offices, Sydney, Melbourne, Brisbane, Adelaide, Hobart, and Perth.

Italian Arsenals.—Tenders are invited for the supply of electric lamps for the lighting of Italian warships, and will be received simultaneously at the Directorates General of Royal Arsenals at Spezia, Naples, and Venice, at 11 a.m. on Dec. 1. The electric lamps to a total value of 40,000 lire (about £1,600) are to be delivered at the Royal Arsenals at Spezia, Naples, Venice, and Taranto. Particulars may be obtained from the Admiralty, Rome.

Colombo (Ceylon).—The Government of Ceylon invite proposals from persons willing to enter into a contract for the supply of electrical energy to the various offices, buildings, and premises of the Government, within the Municipality of Colombo, for a term of years commencing on or about Aug. 1, 1905 Proposals must be delivered at the office of the Colonial Secretary, Colombo, by Dec. 1. The *Ceylon Government Gazette* containing above notice may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament-street, S.W.

RESULTS OF TENDERS.

Barton.—The Guardians have accepted the tender of Mr. E. M. Evans for the electric lighting of the old infirmary at £89.

Wicklow.—The Urban District Council have accepted the tender of Messrs. Blakes and Knowles, at £120, for condensing plant.

Wakefield.—The Guardians have accepted an offer from Messrs. A. Hirst and Sons, Limited, to provide a larger dynamo for £115.

Plymouth.—The Corporation have accepted the tender of Mr. Crabb, coach builder, Union-street, at £15 per car, for painting tramcars.

Brighton.—The Town Council have accepted the tender of the General Electric Company, Limited, for the supply of 31 street police call fire-alarms for £368.

St. Olave.—The Board of Guardians have accepted the tender of the Salisbury Electrical Engineering Company, of Lee, for the supply and fitting up of the electric lighting installation at the workhouse for £365.

Battersea.—The Borough Council have accepted the tender of the General Electric Company for supply of fuseboards, etc., for the lighting of the staircases of the mansions for £19. 6s. 3d.

South African Railways.—Contracts of the estimated value of over £49,000 for electrically-controlled signals have been placed by the Central South African Railways Company with Tyers's electric signalling system.

Blackpool.—The Electricity and Tramways Committee have accepted the tender of the British Westinghouse Company for new 450-kw. traction set (vertical triple-expansion Browett engine and multipolar generator).

Swindon.—The Corporation have accepted the tenders of Bradbury, Son, and Co., Billiter-street, London, and L. Twining and Co., Bristol, for supply and delivery of Somerset small steam coal and Forest of Dean small steam coal at their electricity works.

Digitized by Google

BUSINESS NOTES.

TRACTION.

Ipswich.—The new electric trams were run for the first time on Monday for the convenience of the public.

Shildon.—The United Kingdom Tramways Syndicate intend to apply for powers in respect of this district.

Chatham.—An agreement has been arrived at in respect to certain matters in dispute between the tramway company and the Corporation.

Bristol.—The tramways company will apply in the next session for powers to construct further tramways representing a road mileage of about 12 miles.

Johannesburg.—We are informed that a further contract of over £2,000 has been secured by Hadfield's Steelfoundry Company, Sheffield, for points and crossings.

Londonderry.—The Donegal County Council have given their consent to the construction of the proposed electric tramways from Londonderry to Moville.

Colchester.—A start had been made with the new electric tramways, but the work has been suddenly stopped, the reason assigned being the non-arrival of a consignment of rails from Belgium.

Lancashire and Yorkshire Railway.—It is officially stated that when the Liverpool, Crosby, and Southport line is worked electrically it is only intended to provide first and third class carriages.

Soothill Upper.—The tramway scheme is reported to have fallen through, owing to difficulties in the negotiations with the traction company, and the application for parliamentary powers has been abandoned.

Competition.—It is stated that up to date the City and South London Railway Company have experienced a decline of £8,197 in the receipts for the current half year, due to tramway competition.

Dartford.—The scheme for the construction of an electric tramway system here at a cost, with generating plant, of about £90,713, is to be proceeded with forthwith. A committee has been appointed to take the matter in hand.

Worcester.—The City Council have decided to allow the tramway company three months' extension of time for completing the light railways in St. Swithin's-street, High-street, College-street, Sidbury, London-road, and Bath-road.

Electric Pneumatic Signalling.—We understand that the Nord of France Railway and the Bengal-Nagpur Railway Company have entered into contracts with the British Westinghouse Company for pneumatic signalling installations.

Bath.—The British Westinghouse Electric and Manufacturing Company have secured a further order for 10 magnetic brake equipments for the new cars of the Bath electric tramways. These sets will be duplicates of those already in order.

Sunderland.—At a special meeting of the Borough Council on Wednesday the requisite authority was given for making application for a provisional order authorising the Council to construct new and additional tramways within the borough.

Derby.—The Tramways Committee have under consideration the advisability of running the new electric cars from the Cavendish Hotel and along Wallbrook-road. This route will shortly be recommended to the Town Council for adoption.

Glasgow.—The proposals of the Tramways Committee for the several extensions of the present system (mentioned in our last issue) have been approved by the Town Council. The extension from Crookston to Paisley was opened for traffic yesterday.

Light Railways.—The Board of Trade have confirmed orders made by the Light Railway Commissioners amending the Bere Alston and Calstock Light Railway Order, 1900, and authorising the construction of a light railway in the county of Southampton from Totton to Fawley.

London Traffic Enquiry.—At Friday's sitting of the Royal Commission on London Locomotion, Superintendent Cole, of the E division, gave evidence as to the congested state of the traffic in the Strand, New Oxford-street, High Holborn, Clerkenwell-road, Chancery-lane, Gray's-inn-road, and Theobalds-road.

Lincoln.—Another effort has been made by the Electricity Works Committee to arrive at an amicable settlement with the tramways company. Now only about £250 divides what the Corporation offer and what the company are prepared to accept. It is probable, therefore, that arbitration will not have to be resorted to.

Colne Light Railway.—Major Druitt and Mr. A. P. Trotter have inspected on behalf of the Board of Trade the new line constructed by the Colne and Trawden Light Railway Company. The new line joins on to the Nelson Corporation tramways, and completes a large electric tramway system, joining several of the main centres of population in North-East Lancashire.

Royton.—Among the measures that are being promoted for the next session of Parliament is the Royton Urban District Tramway Bill. Its object is the revival and extension of powers to construct and complete tramways authorised by the Royton Urban District Tramways Order, 1901, the amendment of that order, extension of powers of borrowing, and other purposes.

Doncaster.—Major Druitt has inspected the recently completed tramway to Oxford-street, the new passing place at Hexthorpe, and the extended passing place at Balby-road. The new line to Oxford-street has a total length of 26 chains. Major Druitt expressed his satisfaction with the line, and the cars began to run yesterday. This completes the whole of the lines authorised by the light railways orde 1899, 1902-3.

Electrification of Railways.—Mr. Wilson Worsdell, chief mechanical engineer of the North-Eastern Railway Company, speaking at Gateshead on Friday, said railways in this country were making more rapid progress in electrification than in America, instancing the case of the North-Eastern Company, who are electrifying 47 miles of branch roads, in support of the statement.

Ripon.—At this week's meeting of the City Council the town clerk submitted the draft order of the Light Railway Commissioners for the tramway scheme, the Highways Committee recommending a length of wood pavement 18in. outside the rails between Coltsgate-hill and the Spa Gardens. It was stated that the order would next go before the Board of Trade, who would hear any further objections before giving their approval.

Newport (Mon.).—The question of substituting a motorcar service for the Stow Hill district of Newport instead of laying an electric tramway, as the Corporation is authorised by Parliament to do, it still exercising the attention of the Electricity and Tramways Committee. The tramways manager (Mr. H. Collings Bishop) has been making enquiries in various directions, and has been authorised to pay visits to places where such services are being run to see the working results.

Blackburn.—The half-yearly report—March to September—of the Corporation tramways undertaking shows a loss, after allowing for repayments of capital and interest, of £600. The total loss on the undertaking since the Corporation acquired the tramways four years ago is £21,000. The revenue is gradually improving, however, and certain extensions have lately been entered upon which are expected to prove remunerative. The new tramway proposals of the Corporation provide for an expenditure of £100,000.

Bradwell and Castleton Light Railway.—The Light Railway Commissioners will hold an enquiry into the proposed light railway to Bradwell and Castleton. The proposed line commences by a junction with the Midland Railway near Hope Station, and proceeds through Brough to Bradwell, where there will be a station, and from thence to Castleton, where there will be another station. The entire length will be just under three miles. About four acres of land is to be acquired at Bradwell for the building of a generating station and car-sheds.

Romford.—Plans of proposed extensions to the scheme of electric tramways for the town have been considered in committee by the Urban District Council. It is said that the Empire Electric Light and Power Company are desirous of extending their scheme so as to take the tramways along Mawneys-road to Pretoria-road, along Victoria-road to Squirrels Heath, and from Oldchurch along Hornchurch-road to Hornchurch village. It is understood that the plans were disapproved, and that the Council also did not look with favour on the plans of proposed widenings of South-street and High-street.

Leeds.—At a lengthy meeting of the Tramways Committee a communication was considered from the Wakefield and District Tramways Company, requesting the City Council to grant them permission to run their cars over the Leeds route from Thwaitgate, the terminus of the company's line, to the centre of the city, thus giving a through tram service between Leeds and Wakefield. After considerable discussion the matter was deferred for further consideration. A scheme was brought forward by the general manager, Mr. J. B. Hamilton, to equalise the 1d. stages on the various routes of the Leeds city tramways. In this scheme it is proposed to have a 1d. fare for every two miles. The consideration of this matter was also deferred.

Exeter.—The Board of Trade have appointed Colonel Sir Colin Scott Moncrieff as referee to determine the value of so much of the tramways undertaking as is within the city in connection with the proposed purchase of such lines by the Corporation. At the last meeting of the Tramways Committee the deputation appointed to visit the experimental line constructed by the G.B. Surface Contact Company at Ilford presented their report. The deputation strongly urged upon the committee that both for economy of working and simplicity of management there is no system that can be in any way compared to the overhead trolley. The surveyor and electrical engineer were requested to report upon the first cost and subsequent working expenses of the conduit system and the conduit and trolley system combined.

Paisley.—As a result of negotiations between the Town Council and Mr. Murphy, the promoter of the Paisley and district electric tramways, a compromise has been come to regarding the dispute in connection with the construction of the system in Paisley. Certain concessions have been granted by Mr. Murphy as to the use of setts, and the Tramways Committee have on their side agreed to setts proposed and to withdraw their application to the Board of Trade for the appointment of an arbiter to settle the points in dispute. The work of constructing the system in Paisley will now be carried out without delay, though the agreement meantime arrived at has to be approved by the Council. Already a considerable portion of one of the lines has been laid on the Glasgow-road within the burgh, and the work of laying the double line has been commenced.

Morecambe.—Speaking at the seventeenth annual meeting of the Morecambe Tramways Company, the Chairman said that during the year the directors had given a good deal of consideration to the question of electrifying the line, and had been hopeful, until quite recently, of being in a position to report to the meeting that they had made arrangements with the local authorities to bring this about. He very much regretted that they were not able to do so. There could be no two opinions as to the advantage of electric traction over all other systems for tramway purposes, as it was the most satisfactory means of haulage at present in use, and it was the most suitable for the company and conducive to the interests of Morecambe. The time had come when the local authorities should deal seriously with the ques-

Digitized by Google

tion, and either take the matter in their own hands or grant facilities to the tramways company, or to some other company prepared to electrify the system.

South Lancashire Parcels Service.—The South Lancashire Tramways Company have established a through parcels service between Liverpool and Birkenhead to the various towns on their system, including St. Helens, Wigan, Bolton, Leigh, Prescot, Rainhill, Haydock, Ashton-in-Makerfield, Brynn, Hindley, Atherton, Tyldesley, etc., at rates much below those previously obtaining for the conveyance of parcels. The service has been in operation but a few weeks, and already promises to become popular, the frequent dispatches and prompt deliveries of parcels being much appreciated. Parcels weighing up to 1½lb. each are accepted for conveyance by the tramways company. The rates for the conveyance of parcels weighing up to 3lb. is 3d. each, up to 14lb. 4d. each, 28lb. 5d. each, and so on in proportion, including collection within the area covered by the Liverpool express agencies, and delivery within a reasonable distance of the tramways system, or *vice versa*.

West Riding.—The West Riding tramways scheme is to be revived in the next session of Parliament. The idea is to construct a tramway from the centre of Wakefield to Normanton, *via* the villages of Stanley and Altofts. With Normanton it is intended to connect Castleford, Pontefract, and Knottingley, as well as the smaller communities of Whitwood, Featherstone, Methley, Glass Houghton, Oulton-with-Woodlesford, and Ferry Fryston. Under the present scheme it is intended to make the gauge of the whole system one standard width of 4ft. 8½in., so that one type of car may suit the whole system. This will necessitate the relaying of the lines that have been put down in the Normanton and Castleford districts. The tramway from Wakefield to Leeds is making rapid progress, the contractors having reached Bell Hill—on the Leeds side of Rothwell—within easy reach of the Leeds city boundary. The syndicate has just acquired the Bell Isle Dyeworks, off Sandal-road, which they propose to convert into a power station of some 6,000 h.p. to 8,000 h.p.

Lancaster.—At the meeting of the Lancaster and District Tramways Company on Saturday the Chairman explained the negotiations for the sale of the company's concern to the Corporation. The valuer appointed by the Corporation estimated the concern as worth £30.610, and this did not include stables, horses, etc. The Corporation offered £27,000, but the directors asked for £30,000, or expressed their willingness to themselves appoint a valuer to act in conjunction with the valuer to the Corporation, and to accept whatever sum these two gentlemen decided upon. The Corporation declined those terms and withdrew their offer. Both the ex-mayors of Lancaster and Morecambe had recently expressed their hope that an agreement would be effected, and he, as chairman of the directors, personally felt it would be in the best interests of both sides if terms could be arranged. If the directorate could do anything to bring about that arrangement on fair and reasonable terms, they were anxious to do so. He believed that by electrifying and doubling the line the traffic between Lancaster and Morecambe could be increased six-fold.

Edinburgh.—At a meeting of the Edinburgh Association of Science and Arts last week Prof. Baily referred at some length to the question of changing of the present cable system of tramways in Edinburgh to electric traction. Without discussing whether a change would be advisable or not, he said few people would deny that it was feasible. He alluded to the length and steepness of the hills on certain routes in the city, where the cable system had its advantages, but pointed out that outside the city the hills on most of the roads were comparatively harmless. He characterised the cable to Portobello as undeniably a mistake, and suggested that there should be a continuous line of electric trams through Portobello, Musselburgh, Prestonpans, Aberlady, Gullane, and even to North Berwick. While there was some justification for the cable to Braids, the lines to Craiglockhart, by Gilmore-place, to Gorgie which could be continued to Mid-Calder, and to Slateford, which might eventually go to Colinton, were suited for electrification. The Ferry-road would give a route by which Leith, Granton, and Trinity could be connected to Edinburgh without using the Dean Bridge.

"Three Towns" Scheme.—The Devonport and District Tramways Company have decided to apply to the Light Railway Commissioners for powers to extend their line from the Pennycomequick terminus, *via* Cemetery-road and Ford Park-road, to form a junction with the Plymouth Corporation tramways at Mutley Plain, and also from Pennycomequick, *via* Saltash-road and Coburg-street, to join the Plymouth tramways in Tavistock-road. The company already own the lines from Fore-street, Devonport, to Pennycomequick, from Fore-street to Milehouse, from Morice-square to Camel's Head, and from Pennycomequick to Camel's Head; and they also lease from Devonport Corporation the lines from Milehouse to Tor-lane, from Tavistock-road, Stoke, *via* Stoke-terrace, to Exmouth-road; from Keyham North Gate, *via* St. Levan-road, to Ford-hill; and from Camel's Head to Saltash Passage. The system at present worked by the company is about 10¼ miles, and if the powers now sought are granted they will have about 15 miles of lines. Wherever practicable, the proposed new lines will be double, and we understand that the application will have the support of the Plymouth Tramways Committee. The effect of the proposed scheme will be to connect the three systems of tramways in the Three Towns, and Mr. J. W. Endean, manager and engineer of the Devonport and District Tramways, hopes eventually to inaugurate a system of interchangeable tickets available over all the systems.

Overcrowding of Tramcars.—An interesting debate has taken place in the Bristol City Council on a resolution calling attention to the recent prosecutions against the tramway company for overcrowding their cars. It was suggested that the Watch Committee should be instructed to consider the by-law under which the proceedings were instituted, as on some occasions an excess number of inside passengers might be justified. The chief overcrowding was during the sittings of the Church Congress and at important football matches. At present no extra passenger is allowed, and it was pointed out that the by-laws were made at a time when horse-cars were used, and that their stringency could not apply to electric traction. A speaker instanced what had happened at Plymouth. There a by-law was introduced which permitted certain extra traffic on the tramcars, and in 18 weeks that the by-law was in operation there was an increase in the takings and a saving in management which represented £2,000. That would mean in the course of 12 months £6,000 would come into the coffers of the Plymouth Corporation through a slight alteration in the by-law. If they followed the example of Plymouth, Bristol would immediately be placing in the hands of its tramways company £18,000 clear profit over and above what they were making at present. He suggested that they should ask the tramways company what they were prepared to give in exchange for this valuable concession. It was pointed out that the company were about to go to Parliament for a Bill which would contain fresh by-laws, and the matter dropped.

London County Council.—At the usual weekly meeting of the London County Council on Tuesday the report of the Highways Committee with reference to the erection of car-sheds at New Cross led to some discussion. The first recommendation of the committee was adopted. It was as follows: "That expenditure on capital account of sums not exceeding £91,030 in all be authorised in respect of (1) the erection of the superstructure of the New Cross car-sheds required in connection with the electrical working of the London County Council tramways, and (2) the execution of granite paving works, the laying of rails, and the construction of conduits in and in connection with the car-sheds." A further proposal that the superstructure of the car-sheds should be built by the Works Department without the intervention of the contractor was at once objected to. The estimate for the work was £80,530. Mr. Goodrich moved as an amendment that the committee be instructed to advertise for tenders. The proposition of the committee was, he said, a monstrous one, for the work was to be given to the department without the Council having any particulars before it. It was not to the interests of the ratepayer that the department should carry out this work. Mr. E. White, who seconded the amendment, said recently a contractor erected sheds at a cost considerably under the architect's estimate, and consequently there was a large profit for the tramways. Colonel Rotton supported the amendment, which was opposed by Mr. Torrance, who said it was their duty to offer work to the department whenever the department could undertake it. On a division the amendment was defeated by 80 votes to 23. A sum of £35,000 was also voted for rebuilding the car-sheds at Streatham, in readiness for the time when the cable line from Kennington shall be replaced by electric traction. The committee also had a recommendation in reference to the Elephant and Castle sub-station required for the electrical working of the tramways. In July, 1902, the Council decided that this should be carried out without the intervention of a contractor, on the basis of the priced bills of quantities under which the erection of the Clapham fire brigade station was then being erected by the Works Committee, and the expenditure of £10,725 was sanctioned. The Works Committee, at the request of the Highways Committee, expedited the building work, on an undertaking that in consideration of the exceptional circumstances an extra percentage should be allowed, and the Highways Committee propose to pay an increase of 5 per cent. on the schedule prices. Mr. Williams Benn, in reply to questions, stated that it was not correct that spare men engaged on the tramways were paid 1s. per day less than they received under the companies. As a matter of fact, they were much better paid than under the companies.

LIGHTING AND GENERAL.

Battersea.—Extensions of mains estimated at £665 have been agreed to.

Keighley.—The Town Council have approved the proposed extensions of cables for motor purposes.

Wicklow.—The Urban District Council have sealed an electric light contract with Callender's Cable Company.

Bradford.—The Electricity Committee of the Corporation have decided in future to charge for power on the maximum demand system.

Plymouth.—An enquiry has been held into the Town Council's application for sanction to borrow £41,465 for electric supply extensions.

Whitby.—The Guardians have decided upon the installation of the electric light in the union offices, and tenders will be invited for carrying out the work.

Change of Address.—Mr. James N. Shoolbred, consulting engineer, has changed his address from 32, Victoria-street, to 47, Victoria-street.

Trowbridge.—The Western Electric Distributing Company propose to apply for a provisional order empowering them to supply electricity in the Council's district.

Johnstone.—The Clyde Valley Electrical Power Company propose to apply for power to supply electricity for lighting and power purposes in the burgh of Johnstone.

Brechin.—The offer from the Angus Electric Light and Power Company, Limited, to light the almshouse will be discussed at the next meeting of the Parish Council.

Watford.—The Urban District Council have asked Messrs. Ferranti Limited to overhaul their 300-kw. engine. A supplemental loan of £1,550 is to be applied for in January, 1904.

Gelligaer and Rhigos.—The Rural District Council contemplate asking Messrs. Guest, Keen, and Co. whether they would supply Bedlinog with electric light from their works.

Digitized by Google

Long Eaton.—The Urban District Council have sealed a loan of £5,000 for works of electric supply, purchase of land, etc.

Dunfermline.—The Town Council will oppose the application of the National Electric Construction Company for a provisional order.

Rawmarsh.—The Urban District Council are urging Messrs. Clegg and Sons to take such steps as may be necessary to complete the transfer of electric lighting order within 14 days.

Water Power.—The ancient flour mills at Greenham, Newbury, Whitchurch, and Pangbourne have been purchased by electric lighting companies, who need water power to carry out their undertakings.

Infringement of Trade Mark.—We are asked to draw attention to an announcement in another page referring to the recent decision in the Chancery Court with regard to the use of the word "Simplex."

Whitehaven.—Twenty-one tenders have been received for lighting the workhouse and infirmary with electricity, and referred to a committee for report. The committee have been empowered to consult an expert.

Brierley Hill.—The Urban District Council are asking the Board of Trade to allow a further period of two years, or such time as they would allow, in order that the Council could deal with their electric lighting order.

Widnes.—A special meeting of the Council has been called for Dec. 21 to decide whether application shall be made to the Board of Trade for a provisional order for amending the Widnes electric lighting order of 1901.

Sale of Plant.—Particulars of a sale by Messrs. Weatherall and Green, 22, Chancery-lane, of plant and stock, comprising the complete equipment of an incandescent electric lamp factory, will be found in another column.

Basingstoke.—The Urban District Council have decided that steps be at once taken to promote a Bill in Parliament for powers to borrow £25,000 for electric lighting and free wiring, and other purposes that may be desirable.

Nuneaton.—The Gilbert Arc Lamp Company, Limited, are installing their 6ft. carbon lamp, burning 30 to 40 hours with yellow flame carbons, or 60 to 80 with ordinary carbons, in place of those previously in use in the town.

Londonderry.—The electrical engineer, Mr. Macrory, in his last report recommends, in connection with the private lighting scheme, the purchase of larger fuse-box boards than those specified, to accommodate the meters as well.

Stoke-on-Trent.—An enquiry has been held into an application of the Town Council for sanction to borrow £30,640 for an electric lighting scheme and the provision of a refuse destructor in connection with the electricity works.

Ilfracombe.—On Monday Mr. H. A. Palmer, J.P., the chairman of the Urban District Council, opened the new electricity works at Shepherd's-park. The company started work on Feb. 24, and the first light was switched on May 30

Maidstone.—The Urban District Council have received sanction to the borrowing of £1,770 for purposes of the electricity undertaking. Thirty-seven lamps are to be placed in the various courts and small streets abutting on those streets where mains are at present laid.

Stratford.—The Town Council intend to apply to the Board of Trade for a provisional order to extend the period for doing the work authorised by the electric lighting provisional order of 1901, and to endeavour also to obtain further powers in connection with the subject

Brixham.—The District Council are consulting Mr. E. S. Sanders, Bristol, who is to prepare plans and estimates for a scheme for the electric lighting of the compulsory area, with provision in station plant for extensions, and a scheme for the whole district as now lighted by gas and oil.

Frinton-on-Sea.—The electric light installed by the Frinton and District Electric Light and Power Company was inaugurated last Friday by the High-Sheriff (Colonel R. P. Davis, J.P.). The installation was designed and carried out by Messrs. Christie Bros. and Middleton, electrical engineers, of Chelmsford.

Kensington.—Notices from the undermentioned electric lighting companies relative to proposed extensions of their mains, etc., in the borough, have been agreed to: Kensington and Knightsbridge Electric Lighting Company, Beauchamp-place; Brompton and Kensington Electricity Supply Company, Collingham-gardens, Bina-gardens, and Wetherby-gardens.

Maryport.—The District Council are explaining to the Board of Trade the circumstances which influenced the Council in delaying the carrying out of the works specified in the electric lighting order, giving at the same time an undertaking to proceed with the said works so as to complete the same within two years provided the Board of Trade allowed the provisional order to remain in force.

Stirling.—The last report report by Mr. Hanson, the burgh electrical engineer, shows that for the four weeks ending Oct. 31 the number of units generated was 22,482, as compared with 18,011 for the corresponding period last year. The total number of private consumers in equivalent 8-c.p. lamps connected up to date was 11,263, and for public lighting the number was 12,343.

"Tuffarine" Grey Valves.—We are informed that Messrs. Mosses and Mitchell are making an improved "Tuffarine" grey valve for air and circulating pumps, etc., which will be found even more durable than their well-known "red valves," which have now been in use some 20 years, and are still working most satisfactorily on nearly 6,000 ocean steamers, in addition to stationary engines of all kinds.

Bath.—The last report of the Electric Lighting Committee states that the committee had been informed by Mr. Manville, the consulting engineer, that the boiler foundations at the extension of the lighting station would not be ready in time for the boilers to be fixed and in use for the heavy load, and upon his advice they decided to erect the new boiler *pro tem.* in the old boiler-house at an estimated cost of £250.

Chester.—At a conference, to which all telephone subscribers in the Chester and North Wales district and others interested were invited, on Friday a committee was formed for the purposes of obtaining the support of local authorities throughout the district, and also of the county councils, in obtaining increased telephone facilities.

Southwark.—The Council, in connection with their scheme for extending electric lighting to Rotherhithe, have obtained the Surrey Commercial Dock Company's permission to carry electric cables through the company's premises and across the Surrey and Lavender Docks, subject to an agreement embodying provisions for the protection of the company's interests, terminable at six months' notice, at a rental of £5 per annum.

Northfleet.—The District Council have informed the Kent Electric Power Company, Messrs. Fowler and Co., and the Corporation of Gravesend, that they would assist (at the expense of the promoters) in the promotion of a supplemental or fresh electric lighting provisional order for the district, provided the undertakers would contribute £250 to cover the costs incurred by the Council in obtaining the existing order.

Wilts.—The County Council have sanctioned the expenditure of £6,150 for electrical arrangements at the county asylum as to do away entirely with the use of gas, and increasing electric motor power as well as lighting, duplicating to some extent the electrical apparatus so as to avoid the danger attending breakdown of a single system, and providing for the collection and storage of rain-water in connection with the disused gas-pits.

Stock Exchange.—Applications have been made to the Stock Exchange Committee (1) to appoint a special settling day in and to grant a quotation to the Metropolitan District Railway Company's partly-paid scrip of a further issue of £500,000 4 per cent. perpetual debenture stock; and to allow the Blackheath and Greenwich District Electric Light Company, Limited, 50,000 7 per cent. cumulative preference shares of £1 each, fully paid, to be quoted in the official list.

New Firm.—We are informed by the B. & S. Folding Gate Company that their business, originally started for the manufacture and sale of the B. & S. patent folding gates, has increased to such an extent and other productions introduced by them now form so large a proportion of it that the title, "The B. & S. Folding Gate Company," has become a misnomer, and the cause of misunderstanding. In the future, therefore, the business will be conducted under the name of Arthur L. Gibson and Co.

Frome.—At a special meeting of the Urban District Council on Monday a report was received by the Council's consulting engineer (Mr. F. H. Medhurst) on an offer made by the contractors for the electrical works to light the whole town by electricity at a cost of £849 per annum. It was decided to accept the contractor's offer, and the clerk was instructed to apply for sanction to take up a further loan of £8,500. When this sum has been obtained, the total sum borrowed for the electrical works will be £28,500.

Dust Destructors.—At a meeting of the Leeds Section of the Institution of Electrical Engineers held on Nov. 19 at the Yorkshire College, Mr. S. D. Schofield read a paper on the production of electricity in small towns by the steam raised by the consumption of refuse. He gave the results of some tests. At Cleckheaton, on Oct. 9 last, during a run of eight hours, 51·7 units were generated per ton of refuse destroyed. At Shipley, during a month's run, the result was 37·4 units per ton destroyed, and at Wrexham 37·8 units.

London Gazette.—A general meeting of the members of the British Electric Transformer Manufacturing Company, Limited (in liquidation) will be held at Dacre House, Victoria-street, Westminster, S.W., on Dec. 23, at 12 noon, to have an account laid before them showing the manner in which the winding-up has been conducted and the property of the company disposed of, and of hearing any explanation that may be given by the liquidator, and to determine the manner in which the books, accounts, and documents shall be disposed of.

Glasgow.—The minutes of the Electric Supply Committee submitted at the last meeting of the Town Council recommended that the extension of the Corporation electricity generating station at Port Dundas be proceeded with, but as regarded the additional plant required to be put down within the extended station there and at Pollokshaw-road station the committee recommended that they be empowered, if they thought proper to do so, to appoint a deputation to visit Sunderland and any other English town where turbine plant has already been adopted for generating electricity.

Chesterfield.—At the enquiry last week into an application by the Corporation to borrow £15,000 for electric light and power supply purposes, the Town Clerk said the loan was required in consequence of the growth of the demand for light and power. The committee commenced to supply current in October, 1901, and at the end of December, 1902, £31,274 had been expended. At the end of 1902 there were 192 consumers, who took an equivalent of 15,204 8-c.p. lamps. By the end of October, 1903, there were 291, and a demand equivalent to 22,855 8-c.p. lamps. The demand was still increasing.

York.—The demand for electric light in the city has increased, so that the reserve power at the generating station has for a long time been constantly employed. On Tuesday the continuous working at high pressure told—a cast-iron tee-piece burst. A big load was taken from the accumulators for 25 minutes, and eventually such measures were adopted as to provide an adequate supply, and the police station, the library, the shops, and the streets were enabled to resume their usual brilliancy. When the new extensions to the electric depôt are completed there will be no reason to apprehend a breakdown, but the present state of the plant being made to do more than should fairly be expected of it has existed for over a year.

Digitized by Google

Aberdeen.—Mr. A. R. Bennett, who has acted as general manager and engineer of the Glasgow Corporation telephone department since its establishment, has intimated to the committee that, owing to the many claims upon his time entailed by his outside duties, he wishes to retire from the general managership. The Telephone Committee in their last report recommend that Mr. Bennett continue in his present position until the close of the financial year, and that thereafter he be retained as consulting engineer; that Mr. John Macfee, who has been throughout the assistant manager, be appointed general manager; and that Mr. John MacCallum, who has hitherto held the office of cashier, be appointed assistant manager.

Ham.—The District Council were asked last week to formally consent to the application of the Teddington and Twickenham Electric Lighting Company for an electric lighting provisional order. The company are prepared to insert clauses in the order to give the Council the right to purchase the undertaking at a valuation as a going concern at the end of 7, 14, or 21 years; to supply electricity to private consumers at 6d. per unit for the first hour per day, at the maximum demand or its equivalent, and 3d. per unit for any further quantity. As it would be impossible to insert a clause in the order, the company would be prepared to enter into an agreement to supply electricity for public lighting at a price not exceeding 2½d. per unit. The Council decided to consent subject to the private rate being 6d. and the public rate 2d.

Hamilton.—The lessees for the electric lighting of Hamilton under the Town Council, Edmundson's Electricity Corporation, Limited, whose resident engineer and manager is Mr. T. M. Colson, A.M.I.E.E., announce that owing to the liberal patronage extended to them, having connected 9,000 lamps to their mains in nine months, they have been able to effect a very considerable reduction in their scale of charges both for electric lighting and power. The reduced rate for lighting, which comes into force as from Nov. 1, is a flat rate of 4d. per unit, and for power 2d. per unit for the first hour, 2d. per unit for the second hour, and 1d. per unit for every succeeding hour per day. The company are fitting up five public Gilbert arc lamps for the Town Council's inspection, and on their approval these lamps, it is expected, will be adopted for lighting generally throughout the burgh.

Erith.—It is proposed that application be made for sanction to the borrowing by the Council of a further loan of £5,000, allocated as follows: extensions of mains, £3,000; house services, meters, etc., £2,000. The Electric Lighting Committee have resolved that before any capital expenditure for extensions of mains or other purpose is incurred, the consulting or resident electrical engineers, as the case may be, be instructed to submit to the committee a detailed estimate of the cost of the proposed work; also that the resident electrical engineer be instructed to submit a monthly statement showing the expenditure on capital account to date, the balance of loans unexpended, and the total amount required to complete outstanding works. The committee have instructed the resident engineer to report as to cost of laying a public lighting cable in Lower-road.

Newton Abbot.—A petition of residents of the district of Knowles-terrace asking the District Council to supply proper and efficient means for lighting the road leading from Fern-terrace to Knowles-terrace is before the Lighting Committee; also a letter from Mr. F. C. Pay, engineer and manager to the Urban Electric Supply Company, Limited, stating that he had started to connect up the incandescent lamps in the town, and that he would be ready to connect up the arc lamps probably within two or three weeks. The company had been greatly hindered in their progress with the public street lamps by several persons stopping them from putting their wires to those lamps on the plea that the lamp was private property. As they had to finish a circuit completely before they could light any of the lamps on that circuit, he would be pleased if the Council would come to some arrangement with the owners of such property. They also desired to obtain permission to fix their bracket lamps to the walls of private houses as the gas lamps were fixed at present.

Acton.—At the last meeting of the District Council a letter was read from Messrs. Frank Suter and Co., of Berners-street, W., offering to provide and carry on a complete electric lighting installation for Acton. The conditions are that the cost of building works and installing plant should be borne by the Council, who should also lease a suitable site to the contractors. The latter would carry on the undertaking on behalf of the Council, any profit earned after providing for interest and sinking fund to be equally divided between the contractors and the Council, any loss incurred to be paid by the contractors, but to be refunded to them with interest at the rate of 5 per cent. per annum out of any profits which might be subsequently earned. The Council are given the option of taking over the undertaking at any time, provided one year's notice be given; and the firm offer to guarantee to the Council the whole of the interest and sinking fund of the capital and the whole of any loss which may be incurred. The letter was ordered to lie on the table, the Council having decided to carry out its own installation.

Allgemeine Elektricitaets-Gesellschaft.—From the report for the year ended June 30, 1903, we gather that 8 per cent. dividend has been paid, and the number of workmen employed augmented from 14,897 to 18,278. The factory in the Brunnenstrasse turned out 25 per cent. more dynamos and motors, not counting transformers, the figures rising from 15,283 to 21,850 items, representing 197,327 kw. and 268,100 h.p., against 155,927 kw. and 211,851 h.p. in 1901-2. The largest dynamo made in the year was of 6,000 h.p. Similar increases are recorded with regard to arc lamps, meters, incandescent, and Nernst lamps. The cable works used 10,000 tons of copper; other metals, 13,000 tons; yarn and textile materials, 850 tons; indiarubber and caoutchouc, 200 tons; and insulating material, 900 tons. More important installations for light and power laid down, or in course of erection, included 50 for local authorities, 28 for ships, 50 for mines, etc., 25 for factories, and 10 for theatres; also three for harbours—*i.e.*, Cape Town, Barcelona, and St. Petersburg. Forty other contracts, with an aggregate of 67,540 h.p. and a length of 475 miles of cables, are in hand.

St. Marylebone.—Last night it was asked that a return be presented to the Council showing (1) the total cost of obtaining the Act of Parliament authorising the Borough Council to negotiate for the purchase of the Metropolitan Electric Supply Company's St. Marylebone undertaking. (2) The entire cost of the arbitration, specifying (*a*) the amount paid to the arbitrator; (*b*) counsel engaged, and fees paid to each; (*c*) professional witnesses engaged, and fees paid to each; (*d*) payment to solicitors, and general charges; (*e*) amount paid to electric company for their costs in the arbitration. (3) Costs incurred (*a*) by the Borough Council; (*b*) by the Metropolitan Company as taxed in the action for specific performance before Mr. Justice Buckley, stating if the Borough Council had to pay costs of both parties; (*c*) amount to be paid to the company for works executed since the appointed day for taking over the concern. (4) Amount of counsel's fees for opinions and consultations and other fees and expenses paid or to be paid by the Borough Council up to the end of October, 1903. (5) Total amount paid by the Borough Council or to be paid (including salaries, which are to be specified) to the end of October, 1903, in connection with and in consequence of having obtained the abortive Act of Parliament. (6) From what fund all these expenses are paid.

Derby.—Mr. W. O. E. Meade King, M.I.C.E., has held an enquiry into an application for sanction to borrow £33,400 for extensions of their electricity generating plant and mains, and the provision of generating plant for supplying power to the proposed Corporation electric tramways. The Town Clerk said the loan was required for the extension of the electricity works of the borough, and this had become necessary owing to the growth of the demand for electricity for general purposes, power as well as light, and also in part for the purpose of making provision for the generation of the energy required for the proposed electric tramways. These tramways had just been commenced. Mr. T. P. Wimshurst explained the scheme in detail, and said the area of the particular piece of land required for the battery-house was about 400 yards, and the total area of the land acquired for the baths was about 1,400. He proceeded to state that in the present generating station they had about 4,000 h.p., and up to last March there were 87,000 8-c.p. lamps or their equivalent connected with the station. At the present time the number of lamps connected was about 100,000. The total capacity of the present plant was equivalent to about 110,000 8 c.p., and there was a spare set of machinery for emergency. They proposed to put in a 500-h.p. dynamo for traction and a battery, a 500-h.p. dynamo and another battery for lighting and general purposes, and a 500-h.p. dynamo for reserve for either system. The present spare machine would be brought into use. They were proposing to convert the middle of the town from the alternating to the direct current, and the present system would have no electrical connection with either the tramway or the new lighting extensions. When they had the new plant their total power with reserve would be equivalent to 150,000 8-c.p. lamps. In March, 1901, they had 46,000 8-c.p. lamps connected; on March 31, 1902, 75,972; on March 31, 1903, 87,502; and at the present time 100,000. The proposed plant would probably be working at its full capacity at the end of two years. The present system of lighting had been sanctioned by the Board of Trade, and application had been made for sanction to change the alternating system to the direct three-wire system of 500 volts. Nothing had been included in the present application for mains under the system not yet approved, but application would be made regarding these at a future time. The tramway scheme had been approved, and very little of the present work would be superseded. They had a good gravel foundation for the battery-house. About £2 000 of the loan had been anticipated in boilers, foundations, etc.; the boilers were very necessary, and they could not have gone over the winter without them.

National Cycle and Motor Show.—This exhibition, now open at the Crystal Palace, shows great progress both in quantity as well as in quality of exhibitors. There are over 100 of the best firms in the trade represented, and the secretary (Mr. Frank Peach) has prepared an artistic catalogue with a plan, which serves as an efficient guide to the whole. Light motors form the predominant feature this year. Amongst the novelties we note a model illustrating the original Buckley patent open-sided electric motor wheel for cycles and light cars, temporarily driven with electric motor in centre exhibited by the Buckley Patent Motor Wheel and Carriage Company, 197, Loudon-road, Sheffield, who also show their motor cycles in connection with trailers and governess cars, the advantage being that the person driving is comfortably seated in the latter instead of on a saddle. We are informed that this machine will shortly be put on the market with an electric 2-h.p. motor in the wheel, driven by accumulators placed on the light car, the body of which will be widened several inches so as to accommodate two adults in comfort. The Booth Motor Syndicate, Limited, 19, Grand-parade, Putney, show various types of motor cycles, fitted with a Bassee Michel trembler coil and two accumulators, with two-way switches, in a special case, apart from the petrol tank, and placed immediately behind the engine. Less than 1ft. of wire is to be seen on the machine, practically all the wiring being in the accumulator box. Messrs. J Lacoste and Co., 176A, Shaftesbury-avenue, London, E C., show: (1) An inside wipe contact breaker for motor cycles, the contact being made at the firing point between a steel roller and a tempered steel block let into a fibre ring. The whole is enclosed in a gunmetal casing, made dust-proof and oil-containing, thus eliminating practically all friction. This contact breaker is absolutely self-adjusting, the roller being pressed outwards by means of a spring. (2) An ordinary pattern wipe contact breaker, made with a hammer-shaped blade pressing on a fibre cam, with brass contact piece let in. Its great point is its extreme simplicity and neatness. It is about the size of an ordinary watch, its thickness being well under ¾in. (3) Ignition controllers for testing the firing in each

Digitized by Google

cylinder separately. They are fitted with push buttons, numbered in consonance with the cylinders, so that by depressing any one button the corresponding cylinder is cut out. If three are depressed (in the case of a four-cylinder car), then the remaining cylinder must be sparking if the engine continues to run. When the engine is at rest there is a separate row of buttons to adjust the tremblers. The Woodcote Engineering and Motor Works, Stafford-road, Wallington, Surrey, exhibit current-saving coils, accumulators, charging boards, charging batteries, inspection lamps, and accessories. There is also a new speed-gear by the Variable Gears, Limited, 50, Coldharbour-lane, Camberwell, S E., which is applicable to pedal and motor cycles and motorcars. This is not an interchangeable gear with a number of fixed speeds, but is a true variant with a definite drive, capable of being set to any point between the highest and lowest speeds. The alteration of the speed can be effected without releasing the drive, and consequently should not occasion jars or shocks in setting the gear to any speed. Messrs. H. W. Cocks and Co., 143, Kew-road, Richmond, Surrey, show their accumulators for ignition, made in celluloid, ebonite, and polished teak or walnut cases. All the batteries have the plates well raised from the bottom of cell, and are fitted with non-short-circuiting separators. The accumulators are sealed with composition, and a special acid-proof cement is used, for which it is claimed that it neither cracks nor allows acid to creep to the terminals. The exhibit of Longstreth's, Limited, 427A, Strand, London, W.C., includes lithanode high-rate discharge batteries, electric lighting or traction sets, hand lamps, ignition batteries for motors, etc. Messrs. Charles Peacock and Co, 35, Clerkenwell-road, E.C., have "S" accumulators for 10, 20, and 40 ampere-hours; also traction batteries with special guaranteed acid non-splash vents; also pocket ammeters, voltmeters, and pole-finders, small switchboard instruments, new battery sparking plugs, and speed indicators for car, showing total mileage, miles per hour, and the maximum speed attained during the last 110 yards. Amongst the motorcars a four-seated coupé by the Duryea Company, Coventry, attracted much attention, it being a departure from the conventional models, which still too closely resemble carriages with the pole cut off.

PROVISIONAL PATENTS, 1903.

Nov. 16.

24847. Improvements in or relating to electro-mechanical automatic switches for surface contacts for electric tramways and railways, also applicable for automatic signalling on railways and tramways, and for other similar purposes. Matthew George Waggott, 104, Colemore-row, Birmingham.

24848. Improvements in the electro-deposition of zinc. Sherard Cowper-Coles and Co., Limited, and Sherard Cowper-Coles, 82, Victoria-street, Westminster, London.

24864. Improvements in or relating to electrical clocks. Frederick Augustus Chandler and Bahne Bonniksen, 18, Hertford-street, Coventry.

24905. Improvements in connection with electrolytic cells. Arthur Geoffrey Haddock, 55, Chancery-lane, London.

24909. Improvements in electric lamps and methods of making the same. Charles Proteus Steinmetz, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Nov. 17, 1902, being date of application in United States.) (Complete specification.)

24912. Improvements in and relating to apparatus for utilising electrical energy in igniting, heating, and lighting, or such like uses. James Isaac Ayer, 55, Chancery-lane, London. (Complete specification.)

24914. Improvements in and relating to engaging devices and magnetic lifting contrivances for cranes and other lifting devices. Wolfgang Reuter, 55, Chancery-lane, London. (Complete specification.)

Nov. 17.

25006. Improvements in or relating to electric ignition apparatus for internal-combustion motors and the like. Edmund Woodward Lewis and the Daimler Motor Company, Limited, 18, Hertford-street, Coventry.

25012. Improvements in systems of electrical regulation. Abraham Sandford Adler, 28, New Bridge-street, London. (Complete specification.)

25016. Improvements in electrical storage batteries. Thomas Edward Cornwell, 5, Fenchurch-street, London.

25020. Improvements in or relating to means for automatically governing electric motors, especially applicable for breaking or reducing the current in electric motor vehicles when a given speed of such vehicle is exceeded. Francis Malger Staunton, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

25022. Improvements in couplings for electrical conduits. Adnah McMurtrie, 55, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 21, 1902, being date of application in United States). (Complete specification.)

25028. Improved adjustable electric light pendants or fittings. Montague Herbert Galsworthy and the London Electrical Fittings Company, Limited, Roberts Works, Roberts-mews, Hampstead-road, London. (Complete specification.)

25026. Improvements in magnetic tachometers. Arthur P. Warner and Charles H. Warner, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

25047. Improvements in brackets for telegraph and like posts. Arthur George Bloxam, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Joseph Goffin, Belgium.)

25053. Improvements in electric lighting and power systems. George Gamble Milne, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

25074. Improvements in electrical demand or rebate indicators. George William Lewis Case and the Reason Manufacturing Company, Limited, Norfolk House, Norfolk-street, Strand, London.

Nov. 18.

25087. Improved method and devices for preventing interference in wireless telegraphy and the like. John Gardner, 51, Deansgate-arcade, Manchester.

25098. Improvements in and in the manufacture of terminal fittings for electric cables. James Samuel Foley, 24, Temple-row, Birmingham.

25110. Electric tramcar trolley pole attachments. James Henry Airey, 195, High-street West, Sunderland.

25114. Improvements in or relating to coin-freed electric meters. James Allan, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

25122. Improvements in electric arc lamps. Joseph Barbe Fournier, 178, Fleet-street, London. (Complete specification.)

25127. Improvements in telephone exchange systems. William Aitken, Milton-road, Edge-lane, Liverpool.

25132. Improvements in or relating to electrolytic cells. Edgar Arthur Ashcroft, 111, Hatton-garden, London.

25133. Improvements in or relating to plates for electric storage batteries. Edgar Arthur Ashcroft, 111, Hatton-garden, London.

25146. Improvements in controllers for electric motors. George Laird and John Percival Todd, Westinghouse-building, Norfolk-street, Strand, London.

25150. Improved magnetic ignition device for explosion engines. Gottlob Honold, 322, High Holborn, London. (Complete specification.)

25153. Improvements in or relating to arc lamps. Léon Cibié, 322, High Holborn, London.

25162. Improvements in the electrolytic refining of copper. The Metals Corporation, Limited, and Sherard Cowper-Coles, 70, Chancery-lane, London.

Nov. 19.

25189. Improvements in electric switching devices. Matthew Henry Barber and George Harold Larmuth, 3, Brown-street, Market-street, Manchester.

25197. Improvements in dynamo-electric machines and motors. Wilfrid Robert Vernet Marshall, 121, West George-street, Glasgow.

25222. Protective device for electric circuits. Harry Hay Hornsby and Edward William Anger, jun., 65, Chancery-lane, London. (Complete specification.)

25228. An improved form of electric fuse head and method of manufacturing same. Leonard Percy Asbury, Summerhill, Pickford-road, Bexleyheath, Kent.

25235. Improvements in apparatus for commuting electric currents passing through combined arc lamp and incandescent lamp circuits. Campbell Smart, 65, Chancery-lane, London.

25244. A novel electric lamp. William Phillips Thompson, 322, High Holborn, London. (Ernest Léon Frenot, France.)

25245. New or improved electric lighting system. William Phillips Thompson, 322, High Holborn, London. (Ernest Léon Frenot, France.)

25280. Improvements in electric sparking devices for internal-combustion motors. Laurence Hugh Strain, 46, Lincoln's-inn-fields, London.

25284. A new or improved support for electric cables. Ethelbert Thomas Ruthven-Murray, Norfolk House, Norfolk-street, Strand, London.

Nov. 20.

25322. Improvements in or connected with electrical resistances. Percy Macaulay Ashworth Matthews and Henry Philip Hoghton, 17, St. Ann's-square, Manchester.

25341. Improvements in contact-breaking devices for the electric ignition apparatus of gas, petrol, and the like engines. Laurence William Huber and George Barker Mercer, 34, Castle-street, Liverpool.

25343. A new self-testing electric sparking plug for motors—viz., "desideration plug." Emanuel Myer Goldburgh, 6, Disraeli-road, Forest Gate, London.

25349. New or improved radiator or reflector applicable to incandescent electric or other lights or lamps when arranged as letters and signs for advertising purposes, or when used for lighting. John Alfred Stevens, 114A, Chancery-lane, London.

25362. Improvements in signalling keys. John Ambrose Fleming and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery-lane, London.

Digitized by Google

25381. Improvements in circuit breakers and closers especially suitable for the transmitting instruments used in wireless telegraphy. Marconi's Wireless Telegraph Company, Limited, and Andrew Gray, 24, Southampton-buildings, Chancery-lane, London.

25383. Improvements in the transmitting instruments for wireless telegraphy. John Ambrose Fleming and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery-lane, London.

25386. Improvements in electro-magnetic tremblers. Barthélémy Becker, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

25389. Improvements in magneto-electric induction apparatus. Arthur George Bloxam, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Alfred Schoeller, Germany). (Complete specification.)

Nov. 21.

25451. Improvements relating to arc lamps. Herbert John Haddan, 18, Buckingham-street, Strand, London. (The firm trading as Samuel Zielenziger, Germany). (Complete specification.)

25461. Improvements in apparatus used in wireless telegraphy. Marconi's Wireless Telegraph Company, Limited, Charles Samuel Franklin, Henry Ashley Madge, and Edgar Berry, 24, Southampton-buildings, Chancery-lane, London.

25462. Improvements in transmitting instruments for wireless telegraphy. Marconi's Wireless Telegraph Company, Limited, and Robert Grenville Kindersley, 24, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 10, 1903.

INSTITUTION OF ELECTRICAL ENGINEERS.

Inaugural Address.

BY ROBERT KAYE GRAY, PRESIDENT.

(Concluded from page 723.)

It remains to consider what is, perhaps, the most remarkable feature in recent electrical progress — the development of the electric tramway. The law relating to this branch of the subject is, unfortunately, still more unsatisfactory than that dealing with lighting and power, for the controlling Act is still the Tramways Act of 1870, which was passed before electric traction was introduced, and was intended to deal simply with the ordinary horse tramway. The defects of that Act are too well known to require mention here; the objectionable veto given to the local authorities has once more been sufficient in itself to retard progress to an extraordinary degree. The fact that in the last few years electric tramways have developed so much in this country is not due to the existence of the Tramways Act, but principally to the fact that it was found possible to evade that Act to a considerable extent by promoting these concerns under the Light Railways Act, 1896—an Act which was really intended for another class of undertaking altogether. That Act has proved beneficial to a high degree, as it lowers the cost and simplifies the procedure when a tramway scheme is promoted; but in the years during which it has been in operation various defects have been discovered, and attempts have from time to time been made to have them remedied. My predecessor, Mr. Swinburne, pointed out these defects to the President of the Board of Trade when our deputation waited upon that Minister last year, and here, again, we were promised a measure to remedy them. A Bill *was* introduced this year, but it was unsatisfactory in the extreme, as it made no attempt to deal with the whole subject, but merely tinkered at one or two details, and we cannot regret, therefore, that it made no progress. The Board of Trade had previously appointed a committee to consider what amendments of the Act of 1896 were desirable, and as the President of the Board of Trade told our deputation that a report had been received from that committee, we naturally expected that the new Bill would deal comprehensively with the subject, but in this we have been disappointed. The old Tramways Act ought to be repealed and replaced by a measure suitable for modern needs. Under the Light Railways Act the powers of the Commissioners might with great advantage be extended. At present they are hampered by the feeling that, if not bound by the letter of the Tramways Act, they must, as far as possible, respect its spirit, and hence the absence of consents from local authorities has more weight than is proper. In cases where a light railway scheme is likely to compete with an existing railway company, the provision that the promoters must proceed by private Bill, and not by an enquiry before the Light Railway Commissioners, also militates considerably against the usefulness of the Light Railways Act by curtailing the powers of the Commissioners, and this restriction ought to receive attention in any amending measure.

These are but a few of the numerous points in the present law which call for attention. The whole of our electrical legislation is in urgent need of reform, and, after so many promises have been made, it will be very regrettable if nothing is done to remove the existing defects. While the electric light and power undertakings have obtained but little legislation in their favour, it is a relief to see that Parliament has granted railway companies certain advantages. By the Railways (Electrical Power) Act, which received the Royal assent on Aug. 14 last, existing railway companies, desiring to convert any of their lines to electric traction, are enabled to obtain sufficient powers for so doing by means of an order of the Board of Trade. They may become interested in power companies, and may take from them electrical energy for the supply of their main or branch lines. In spite of the legal impediments referred to, it will be found on investigation that substantial progress has been made in Great Britain in the utilisation of the electric current for both light and power purposes Exclusive of traction motors, in March of this year, lamps and motors equivalent to over 14,000,000 8-c.p. lamps were connected to the mains of public electricity supply undertakings, the Metropolis being represented to the extent of about 5,000,000. There were about 300 towns enjoying the advantage of an electricity supply, this number including, with two exceptions, all the towns whose population exceeds 100,000. The exceptions were Tottenham and the Rhondda district, which did not seem anxious to be alongside of their 38 fellows. It appears that at this period, exclusive of power companies, the public supply stations had motors amounting to 55,000 h.p. connected to their mains. Municipal undertakings own generating plant of a rated capacity of 320,000 kw., and private undertakings are represented by 160,000. In the Metropolis the companies are proprietors of about 100,000 kw., whereas the public bodies are responsible for approximately 28,000. The pre-eminence of the companies in London is due to the fact that they acted as the pioneers and were first in the field. The average rated capacity of a British station appears to be about 1,400 kw. It is to be remarked that, while in the provinces the average municipal station has a capacity of nearly three times that of a company station, in the Metropolis the ratio is reversed. Again, the average metropolitan company has, approximately, 10 times the plant capacity of the average provincial company.

It is interesting in this investigation to note that modern tendencies in this country are decidedly in favour of the direct-current system with a three-wire distribution. The number of direct-current undertakings increased from 139 in 1901 to 214 in 1902 and 260 in 1903. For these three years the alternating-current stations numbered 67, 68, and 69 respectively. There are now established in Great Britain 13 two-phase and 5 three-phase stations, exclusive of power transmission stations. In 29 cases supply is given on two or even more systems. Many of the alternating-current stations have taken up the supply of direct current, others have added two-phase or three-phase supply to their single-phase service, or have changed over completely to one of these. The direct-current system appears to be in no immediate danger of supersession, in part owing to the raising of the voltage, and the consequent possible extension of the service area. The number of voltages in use is somewhat confusing, and presents to the Standards Committee a difficult problem to solve. These voltages now amount to about 16, and out of 289 examples of pressures nearly one-third are declared at 230, more than one-sixth are given as 220, while voltages of 240, 200, and 100 claim about one-eighth each. There are between 50 and 60 stations which revel in more than one declared pressure. The extent to which the change from one voltage to another has taken place may be judged from the fact that in 234 cases the pressure is upwards of 200 volts; 64 supply current both above and below 200, and there are only 29 whose supply is entirely under 200 volts.

Although at the present moment the efficiency of carbon glow lamps and, in certain cases, of arc lamps is not so great at the higher voltages, yet it cannot be gainsaid that the change of voltage has been a beneficial one both for the supplier and the consumer. The supplier has benefited through a more profitable use of his current conductors; this benefit has considerably more than outweighed the expenditure in other directions that the change entailed. In many cases one of the large expenditures must have been in the purchase of storage batteries, for it appears that out of 330 stations no fewer than 240 use these batteries to a greater or less extent. The only drawback to the change would appear to exist in the case of small motors. Some remarks on the methods of charging for current could be made, but I limit myself to pointing out that the number of lighting undertakings in which the maximum demand system is employed alone is now 104, as compared with 114 in 1902, or, say, 31½ per cent., instead of 40 per cent. of the totals of the respective years. The maximum demand system, in conjunction with one or more other systems, is used in 74 cases, as against 38 in 1902, or, say, 22½ per cent., as compared with 13½ per cent. A simple uniform rate gives the corresponding figures of

Digitized by Google

70 and 63, representing 21½ per cent., against 22 per cent. I regret I have not been able to collect information with regard to private installations in Great Britain which would prove sufficiently comprehensive. I have therefore decided to leave this portion of the subject alone. There is still room for improvement in the carbon glow lamps. I am given to understand that 16-c.p. lamps for 200 volts and upwards, with a life of 1,000 hours at an average consumption per candle of even four watts, can hardly be obtained as a commercial article. The production of the Nernst lamp seems to be improving, and its employment in a large number of towns for street-lighting, and in many private installations, will enable people to thoroughly appreciate its merits and utility. I find that the most recently introduced pattern gives three-quarters of a candle per watt when new. Nernst lamps are used by about 1,000 supply companies in the United States, the Hartford (Connecticut) Company alone employing about 4,000. In many cases these lamps are maintained by the supply company without extra charge, or at a nominal cost. The osmium lamp of Auer von Welsbach is well spoken of for low voltages in some quarters. Twenty-five to 30-volt lamps have been made which show little diminution in light-giving power after 800 to 1,000 hours burning. Apparently they absorb about 1·5 watts per candle, but are expensive to purchase. We shall doubtless hear more of the mercury vapour lamp associated with the name of Mr. Cooper Hewitt.

While with alternating-current work the tendency is always to simplify the switchgear to the utmost, this does not seem to be universally the case in direct-current practice, at any rate in the smaller public supply stations Some of these have elaborate plug boards, numerous 'bus bars, expensive battery regulators, and all sorts of alternative ways of doing the same thing. In many cases where these complications do not exist, not only the comfort of the staff but the efficiency of the service are greatly increased. It appears to be forgotten that everything tending to simplicity has a beauty of its own which no complication can ever rival. In spite of the absence of any notable development in switchgear, a very high standard has been attained by British designers, especially in heavy power and lighting work with alternating currents at high pressure. Following a totally different line from the Continental and American practice, our engineers have evolved apparatus which is at the same time safe, simple, and reliable, while occupying a minimum of space. In the early days of the electrical industry when the range of possible distribution of current was restricted, the engineer had to seek a site for his generating station in crowded and expensive districts. To economise space he employed high-speed reciprocating engines and water-tube boilers. At that period he could doubtless do this with advantage, as the generator units in use were, comparatively speaking, small. To-day the units are larger and the range of possible distribution is increased. It is not, therefore, so necessary to follow the old practice, and in many cases to do so is inadvisable.

Among the remarkable things of the year may be mentioned as in course of construction four turbo-generators of the Parsons type, each rated at 5,500 kw. to 8,280 kw., and occupying a space measuring only 51¾ft. × 14ft × 12ft. A 6,500-kw. turbo generating set is being built by Brown, Boveri, and Co. which measures 59ft. × 10ft. × 10ft. A Curtis turbine of 5,000 kw. is running in Chicago; this turbine is a combination of the Parsons and De Laval systems, and is arranged with a vertical shaft, a somewhat inadvisable design. In shape it is cylindrical, and, including turbine and generator, stands 25ft. high, with a diameter of 14ft. It may be interesting to note that there are over half a million horse-power of turbines in use or on order, and 24 stations in this country use the turbine more or less. While referring to large units, it may be of value to state that the Société Cockerill of Seraing is expected to show at the St. Louis Exhibition next year a gas-engine of 3,000 h.p.; this engine will have two cylinders, each of 51in. diameter, and will run at 85 revolutions per minute. It is said that the Gasmotoren Fabrik Deutz is designing a 6,000-h.p. engine.

With relation to electric driving in factories and ships, we all remember the excellent papers read before this Institution by Mr. Williamson and by the late Mr. C. E. Groves. The contribution of the latter was especially interesting to me, as it showed in a striking manner the progress in the employment of the electric current on shipboard from the time of the Silvertown Company's installation on their cable steamer "Dacia," in 1879, down to the huge developments already reached at the time the paper was read.

Among the recent varied uses to which electromotors can be put may be mentioned gold-mining at the Klondike, where they are employed in dredging, washing, and conveying the material to the tip. Another instance is the driving of a rolling-mill, where a 400-h.p. motor is coupled direct to the rolls. In a large plate-glass works in America there are four generating sets of 4,000 kw. each and one set of 350 kw.; there are also 20 motors of 450 h.p. each and 20 of 200 h.p.; the three-phase system is in use at 5,800 volts with frequencies of 40 and 25 cycles per second. A large colliery in the same country has plant of 2,900 kw., the installation comprising 44 mining locomotives and 75 miles of underground trolley wire; the power is transmitted at 5,600 volts, three-phase, 25 cycles per second, but is converted for use at 275 volts. At the Carnegie Works electricity is used for almost everything requiring power, and it is stated that in the Homestead Steelworks of Pennsylvania, by the aid of electricity, 4,000 men make as much steel as is made at Krupp's with 15,000 men.

Since the establishing of the Portrush electric tramway in 1883 the electrical engineer has encroached on the field of the tramway engineer, and consequently the purely tramway work, as apart from the electrical work, has often shown the mark of the active, clever, but untrained mind, impossible curves and grades being attempted, and unnecessarily expensive work being done. There has been some advantage in this no doubt, as the experience gained by these works, although expensive, has tended to improvements in practice. There is an American manner in this mode of procedure which leads to a free use of the scrap heap The individual suffers, but the community eventually gains by the survival of the fittest. It is, I suppose, a rule which applies and must apply to all young nations and industries. The rough and tumble while it lasts is interesting and exciting, and doubtless drives the workers to put their best foot foremost. The golden rule, "Be sure you are right and go ahead," is the best to follow, but it often happens that one dies and is taken from the arena before even the first part of the rule is complied with. On the whole, therefore, it is perhaps as well that chance should be allowed to play its part, and that activity and energy should not be troubled with a too severe bearing-rein. The rule before cited should probably be modified in the manner of the saying of the northern farmer to his son, and should read, "Be sure you are right and go ahead, but go ahead." I think this has been the motto that has been adopted by electrical engineers since 1877, with the much-desired effect that sufficient improvement has been made to enable the electrical bark of this country to be steered into still water for a time. This happy condition does not, I believe, exist in Germany or America, where apparently there are "more heads to be broke." We have been toiling up a steep hill for many years, and the time has now arrived when we should stop and survey the landscape as a whole, instead of narrowing our view to the particular point towards which we happen at the moment to be ascending. Already many of the paymasters are questioning the scrap-heap theory, as they know by experience that this is often evolved from nothing but a craving for change and a want of appreciation of the true value of money on the part of their advisers. I make these remarks with no desire to convey the idea that work in this country is not carried out conscientiously and well, but rather with the view of suggesting a curbing of the expenditure of money which produces a semblance for the moment of unbounded prosperity, while in reality it only means riding full gallop for a fall. If the fall should occur, the many men who are entering our ranks every day and swelling our numbers will find their prospects blighted owing to a disturbance of the trust which is placed in the

Digitized by Google

electrical engineers of to-day by those who supply the sinews of war. I, therefore, think it incumbent on every electrical engineer to carefully weigh every recommendation he may make, not from the point of view of immediate, but rather from that of ultimate efficiency, and to deal with every possible factor in drawing his estimates. The papers read, and the discussions which take place in this hall, and in the meeting places of our local sections, tend to this end.

I am afraid I am wearying you by reiteration, but I feel strongly on this subject, which, in my opinion, affects the vital interests of the Institution, and I venture to lay before you things that, though perhaps to many of you are platitudes, may prove of use to our younger colleagues. The establishing of electrical tramways, and the electrification of existing railway and tramway lines, are rapidly assuming great proportions, and it is not difficult to predict that this branch of electrical engineering will continue to advance by leaps and bounds, providing employment for many electrical engineers connected with the Institution. From the report of the London County Council on the excellent work they have been doing in South London, it would appear that the difference in prime cost between laying an urban line on the conduit system and construction on an overhead trolley system, is not so great as to render the former altogether impracticable. I think, therefore, those authorities in the municipal areas are acting in the best interests of the inhabitants of this crowded Metropolis who refuse to authorise the erection of the unsightly, and in many cases dangerous, overhead conductors. The utilitarian may argue that whatever increases prime cost goes in restriction of development, and in this he is to a certain extent correct. But apart from the question of danger avoided, it is usual in civilised communities to have some respect for forms and appearances as well as for the purely useful. Moderation should reign in all things, and in relation to electrical tramways, London does better to employ the conduit system and follow the example of Budapest and Paris, rather than erect an overhead system similar to that which disfigures my native city of Glasgow and many other towns in this country. The conduit system has cost London per mile of single line about £14,000, an overhead installation would have cost £7,000. In my opinion the difference is well spent. It may be argued that this difference does not represent the whole difference, and that many electrical arrangements can be made in an overhead system that would not be permitted in a conduit system. My answer to this is that it comes within the province of us engineers to overcome these difficulties—overcome them we shall if we only apply ourselves seriously to the task, and produce results which will pass the severest test that the Home Office, Board of Trade, or other authority may impose.

Passing on to the nature of the current supply, the continuous current system predominates at present in Great Britain for all kinds of electric traction. Its supremacy is again being threatened by the monophase system, whose employment in certain cases possesses advantages that are greater than the disadvantages. The efficiency for traction purposes of polyphase working has not been sufficiently proved, but as regards the method of transmitting power to considerable distances for conversion to continuous current to be applied to tramway purposes, the three-phase system has so far held the field at pressures up to 6,500 volts. A most complete system of high-pressure polyphase traction work was inspected by many members of the Institution during a visit to Northern Italy in the spring of this year, and to those interested in this subject it will be useful to closely follow the fortunes of the electrified Valtellina, Lecco, and Milan Railway. For this line there are in course of construction electric locomotives which have been designed to exert a tractive force of from 7,500lb. to 11,000lb. at a speed of 40 miles per hour, their individual output being, I understand, from 800 h.p. to 1,200 h.p. The exceedingly interesting experiments being made on the Marienfelde-Zossen military railway have resulted so far in the attainment of a speed of 125 miles per hour. The railway from Berlin to Zossen is about 15 miles in length, and the current generating station is about eight miles from the head of the line. The car—a Siemens and Halske design—was supplied with power from the line wire at a pressure of about 14,000 volts.* The inauguration of through traffic between Liverpool and Bolton, a distance of 40 miles, marks an important epoch in the progress of the South Lancashire Tramway project, which embraces a network of more than 500 miles of track, and will serve an area whose population is about 5,000,000.

The application of electric traction to our railways is progressing. At present the sections which are being dealt with are those which have a great traffic density or a frequent service This policy is doubtless a wise one, as the railway companies limit the application of a considerable capital expenditure to the best paying division of their lines, and to those portions where the benefits to be derived are the most apparent. During the current year the first section of the Metropolitan District Railway conversion has been made, and it is expected before March of next year that the Moorgate street - Drayton Park and Drayton Park-Finsbury Park sections of the Great Northern and City Railway Company will be in operation. The Mersey Tunnel Railway has been completed, and the conversion of the Wirral Railway is under consideration. The North-Eastern Railway has had trial runs along Tyneside, and good progress is being made with the Liverpool-Southport line. The Central London Railway is completing the change from locomotive to motorcar driving. The motorcar system is generally accepted as the best form for passenger traffic for many reasons which I need not recapitulate. The direct-current system at 500 to 700 volts appears to remain as a standard for railway work of this class, as well as for tramway work, but there are signs that single-phase alternating current may prove a rival. In the United States the Washington - Annapolis Railway is being equipped with an overhead system which will deliver direct to the motors a single-phase current at 3,000 volts. The three-wire system of feeding tramways and railways, though not without examples abroad, has not been adopted in this country save on the City and South London Railway, where it seems to have proved satisfactory.

The only surface-contact system in this country is that which has had nearly a year's trial at Wolverhampton. Troubles have arisen between the Corporation and the company. It is therefore impossible to say exactly how the matter stands. It is believed that the Kingsland mechanical switch surface-contact system may be tried at Dresden shortly. Although accumulators are being extensively used for private carriages in London and elsewhere, yet this country has not seen its way to employ them for rail or tramways. In Italy and Germany some use is made of them, and it is stated that as the result of two years' working on lines running out of Bologna, the cost of battery traction has proven 28 per cent. cheaper than steam. The use of storage battery locomotives in America for shunting and mine work appears worthy of mention, as it seems to have attained considerable proportions and to have proved successful in practice.

In the provinces the great power distribution undertakings are getting to work by degrees. Besides the Midland and Newcastle concerns we can now count the Durham, Lancashire, North Metropolitan, and South Wales Companies. The advantages of electricity as a motive power seem to be readily appreciated by the industrial populations of these districts. Among some of the large schemes in project is the electrification of the national railways of Sweden, the original power being derived from water pressure or the combustion of peat. Estimates are being drawn for 2,700 miles of railway, calling for over 100,000 h.p. The official estimate shows that there will result a saving of 50 per cent. in the present working expenses, which amount to about £800,000 per annum. Switzerland again speaks of a conversion of its national lines, entailing the use of 30,000 h.p. to be obtained from water pressure.

The utilisation of the Victoria Falls of the Zambesi is a project under serious consideration, and at least a portion of the scheme may be near realisation. Some three months

* Since writing the foregoing I notice that the car designed by the Allgemeine Electricitäts-Gesellschaft has on the same line attained a speed of 130½ miles per hour.

Digitized by Google

ago certain details of the scheme were made public, and from these it appears that whereas the Niagara Falls are equivalent to a continuous loss of 7,000,000 h.p., at the Victoria Falls of the Zambesi the loss is five times as great. In advocating the utilisation of this waste it is pointed out that tramways near San Francisco are driven by a current which has its origin in the Ubax Falls about 220 miles away, and that some American engineers estimated that power giving a steady load of 24 hours per day could be delivered 330 miles from the generating plant at about £4. 10s. per kilowatt. At Niagara six syndicates are carrying out work which, when completed, will be capable of generating over 1,000,000 h.p. Some of the generating sets will be of 10,000 h.p. working at 11,000 volts. The pressure will be converted to 60,000 volts. The highest pressure as yet made use of in Europe for power transmission is in Italy—namely, 40,000 volts. This plant is not yet completed; it is intended that water power will develop 7,500 kw. at 9,000 volts (42 cycles per second), which will be transformed to 40,000 volts for transmission. In the United States, in Montana, where a similar pressure is employed for transmission, the voltage was increased to 80,000 for a few hours with success. Consideration of these voltages recalls the experiments made in March, 1883, just 20 years ago, by Marcel Desprez, in power transmission between Paris and Creil, a distance of 57 km. at a pressure of 5,700 volts. One also thinks of the transformer of Gaulard of about that period.

I now turn to the subject which gave birth to this Institution and from which its first title was derived—I mean the subject of telegraphy. Between May 26 and July 7 of this year an international conference of the telegraph administrations was held in London at the invitation of his Majesty's Government. These meetings are, so far as may be, quinquennial, and are usually held in the capitals of the Great Powers. The last meeting in London took place in 1879. The discussions which now are carried on between the Government delegates, and with the representatives of the telegraph companies who are also invited to be present, are purely of an administrative order, and principally deal with tariffs and the rules for carrying out the international exchange of telegrams. Technical questions, such as the size of conductors and the classes of instruments to be employed in the international service, are either already agreed upon or are the subject of separate and private understandings between the administrations interested. These have been fairly well standardised during the 38 years that have elapsed since the first conference was held in Paris. Since 1879 the growth in the length of telegraph land lines has been very large, and the development of submarine telegraphy has been almost phenomenal. At that date the public were just beginning to realise what power for good or for evil was being placed at their disposal. Merchants were beginning to feel that the submarine telegraph had a centralising effect which enabled them to carry on their business with smaller stocks of goods. The large merchant had no longer the control of the foreign markets which his wealth had formerly given him, and the small merchants began to have an innings. When this state of things came home to the traders, submarine telegraphic facilities were in great demand. The cables across the Atlantic and other oceans began to multiply, and new centres of industry were connected to the chain. The men at the head of cable affairs, and notably the late Sir John Pender, were not slow to meet these developments by increasing the ramifications of the telegraphic network, and bringing the charges for telegrams to such a figure as to encourage the public to make full use of the means of intercommunication placed at their disposal. This policy was hastened by the wholesome dread of competition where such did not exist, and by competition itself. A year ago the gap in the world's telegraphic girdle was completed by the laying of the Trans-Pacific cable which now unites Canada with Australia, and this year has seen completed a second line across the Pacific from San Francisco to the Philippines and China by way of the Sandwich Islands, Midway, and Guam.

It is strange that during this development the improvements in the types of telegraph cable employed have not been great, nor has there been any great advance made in the design of the instruments used for the transmission of signals, but the administrative work has been vastly bettered. Messages which formerly took hours in transmission are now received from the public and delivered to the addressees in a few minutes. I am informed that a telegram announcing the result of the yacht race for the America Cup was carried, in August last, from London to South Australia in four minutes. This message, which was forwarded *via* South Africa, was handled by 15 operators, passed through 11 stations, and traversed 14,404 nautical miles of submarine cable and 1,515 statute miles of land lines. Ordinary commercial traffic cannot be dealt with at this speed, but the instance I quote shows what can be accomplished when special arrangements are made to carry news which is of peculiar interest. The manager of an American cable company has told me that the result of the America Cup Race reached London one minute after the termination of the race, having been transmitted through 3,400 nautical miles of submarine cable and some 200 statute miles of land wire. The record time between New York and London is 30 seconds, and messages have been sent and replies received in 1 minute 30 seconds.

During the last 25 years the engineers engaged in submarine telegraph work have devoted more care to the surveys of route than was previously the practice; to a great extent this means that the engineers have succeeded in persuading the capitalists that these surveys are of prime importance. The Atlantic cables of 1857-8, of 1865, 1866, and on to 1874 were laid on the data as to the ocean bed furnished by perhaps 30 soundings taken over a route some 1,700 nautical miles long. In 1871, Lord Kelvin furnished a means for sounding which did not exist previously, and in 1872 the Silvertown Company made a first trial. The late Sir William Siemens, in 1874, carried out the first systematic sounding in the Atlantic, and from that time forward until 1883 it was the habit to take soundings, but not to make a full and careful survey. With the results obtained from these soundings our knowledge of the ocean bed was increased to the extent of teaching us that submarine mountains, plains, and gullies exist, and that the physical conditions of the submarine floor are very similar to what one observes in travelling through Europe from Calais to Brindisi. In 1883 the first thorough preliminary survey of any cable route was made, but as this has been the subject of a paper read before the Institution on Nov. 10, 1877, I need not enter into detail further than to say that the result of this survey materially altered the original plans for laying the cable on account of unsuspected elevations and depressions of the ocean floor having been discovered. In addition to the configuration difficulties to be encountered by a submarine cable, the chemical composition of the soil is important, as it greatly affects the cable's life. A paper referring to this subject was read before the Institution on March 11, 1897. I had the pleasure of handling about a month ago a piece of submarine cable which had lain at the bottom of the sea in deep water for nearly 30 years, and its appearance was such that I was unable to say whether it could not have lain there for another 30 years without showing any deterioration. To-day there are employed in cable work 49 ships, representing 92,094 tons. The largest, the "Colonia," belongs to the Telegraph Construction and Maintenance Company, and has a dead-weight capacity of 11,000 tons. When he considers the comparative facility with which cables are now repaired, no shareholder in a submarine telegraph company needs fear for the permanency of his property. In July, 1879, there were 50,450 nautical miles of cable in operation; there are now under the sea 222,253 nautical miles, and I have every reason to believe that this mileage will continue to increase.

On wireless telegraphy I have no new developments to report. The Cantor lectures delivered by our vice-president, Prof. J. A. Fleming, before the Society of Arts in March of this year, and the description of the Lodge-Muirhead system in *Page's Magazine* for last May, give to anyone interested in the subject the latest communicated information of any value. I need only add that there seems no immediate prospect of its seriously competing with the business of the existing telegraph companies. In

Digitized by Google

my remarks concerning the means of transmission through submarine cables, I omitted to make reference to the relay of Mr. S. G. Brown which was described by him in the paper he read before the Institution on May 1 of last year. I may also mention that since 1879 considerable improvements, though of a minor nature, have been made in duplex transmission.

The use of the telephone continues to extend, and in addition to the greater facilities offered in Great Britain there are gradually being established international wires which place in telephonic communication the principal towns of Great Britain and several of the commercial centres on the Continent. So far as I am aware, no practical use has yet been made of Poulsen's teleautograph which I had the pleasure of inspecting with our vice-president, Mr. Gavey, and of which he gave a description in a communication to the Institution on Nov. 22, 1900.

Before passing to the next portion of my subject, I should like to make a short reference to a very early investigator into the phenomena of magnetism: I mean Dr. William Gilbert. Our past-president, Dr. Silvanus Thompson, who has taken so great an interest in the bibliography connected with Gilbert, tells me that the tercentary of the death of this remarkable man will occur on Dec. 10 next (new style), and that probably some notice of the fact will be taken by his native town, Colchester, and by the Royal College of Physicians, of which body Gilbert was president at the time of his death. As you are doubtless aware, the work by Gilbert, notably his "De Magnete Magneticisque et Magno-magnete Tellure," shows a patient observation and careful recording of results, which resemble in many ways the method of Michael Faraday. Your Council have not yet decided what steps, if any, will be taken by the Institution in connection with this celebration.

Whilst reviewing the state of electrical progress, mention should be made of the work of the Engineering Standards Committee. This committee is making some progress in its work, and it is pleasing to note that the Government has recognised that the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Institution of Naval Architects, the Iron and Steel Institute, and this Institution should be assisted in the useful work they are doing. A Government grant has been made which will lighten the burden of these institutions, as, until this assistance was recived, they were not only doing the work, but were also providing the funds necessary for carrying it out. Sir William Preece and Colonel Crompton, two of our past-presidents, are members of the General Committee, and represent the Institution. The former is chairman of the Electrical Plant Divisional Committee, which is most directly connected with our branch of the subject. It is to be hoped that some of the results of the deliberations of the Electrical Plant Committee may shortly be published, and should they be, I shall append them to this address by way of further publication.

While speaking of the work of the Engineering Standards Committee, I cannot resist the temptation to protest against the continual attempts which are made to apply to our weights and measures and money what is called the decimal system. However regrettable it is that scientific men should not have boldly recommended for adoption 12 instead of 10 as the place ratio of figures when so many sweeping changes were made at the time of the French Revolution, I am afraid they are too indolent to do so now, and that 10 will continue in use until another universal upheaval changes all things. Because 10 is conventionally adopted for this ratio, there appears to me no reason why the system should be extended to all the weights and measures necessary for common use, bringing about many absurdities, and in many cases establishing very inconvenient standards. The adoption of the metre, or any other measure of about its dimensions, as a unit of length matters little, but if the metre be adopted it is no reason because a millilitre of distilled water is supposed to weigh 1 grm. at 4deg. Celsius *in vacuo* that butter, coal, diamonds, and wood should be compulsorily dealt with in metres or their decimal derivatives. I am the first to admit that in physics and chemistry there are undoubted advantages in having, so far as one can, a common relation existing between the various units, but that is no reason why we should combine to force on the public a system of weights, measures, and money which is so much against nature that it hardly obtains currency in the countries of its adoption. In France, precious stones are to-day bought and sold in carats, firewood in cordes, milk in pints, gravel in toises, grain, potatoes, and charcoal in boisseaux, wine in barriques, feuillettes, demi-setiers, and chopines, wood for construction in pieds, pouces, and lignes, beer in canettes and pots, sugar and coffee among the poor people are dealt with in livres, demi-livres, etc. Cattle dealing is carried on in pistoles and écus, and not in francs. Finally, they have just issued a 25-centime piece, doubtless because it represents a quarter of a franc. In my opinion, the decimal system applied to weights and measures and money offers too limited a field for the operations of ordinary life; and I should be sorry to see it with all its disadvantages forced upon us by legislation to the exclusion of other systems, when the admitted advantages to be gained are so small.

I should now like to make a few remarks, if time will admit, on the present functions of electrochemistry. This is one of the most progressive branches of electrical industry; although striking advances are rare, constant improvements in detail are being made, and processes which have been long outlined are being developed into commercially practicable methods. Probably there has been no step so noteworthy during the year as the announcement by Mr. James Swinburne of his invention of a new process for the reduction of metallic sulphide ores, which, with the collaboration of Mr. Ashcroft, he has put to test on a commercial scale. The process consists in treating the ores with chlorine, displacing the sulphur, which is recovered—the essence of the invention being the fact that this reaction takes place without the formation of chloride of sulphur; various precipitations follow, according to the metals present, the final result, after all the other materials have been extracted, being zinc chlorine. This is electrolysed, the zinc being obtained in the metallic state, and the chlorine is ready to be utilised again. Thus the process is cyclic, and it is applicable to almost all kinds of ores, including the huge piles of waste which have accumulated as the result of less complete processes. This system may well prove of the utmost importance in metallurgy. Another valuable process which has made considerable progress during the past year is the reduction of iron ores by means of the electric furnace. At Livet, in France, the process is in practical operation, generators of 1,200 h.p. each giving single-phase current at 30,000 amperes each, and driven by water power, being employed. The output is 12 tons of steel per day. At these works ferro-silicon is also made from quartz, scrap iron, and coke at less cost than that of smelting, and copper pyrites is reduced to copper and iron sulphides rich in copper, and ready for the ordinary smelting process. Steel of high quality is similarly produced in Sweden at the rate of 1,500 tons per annum. With the Stassano process the expenditure of energy is said to be 3,000 horse-power hours per ton of iron; but with the Ruthenburg system it is said that 500 kilowatt-hours suffice, and that ores of poor quality can be treated. Large deposits of iron ore exist in Canada remote from coal mines, but within reach of Niagara Falls, and it is said that a Canadian syndicate has been formed to work the Ruthenburg system with power derived from the Canadian Niagara Falls hydro-electric works. Already in Canada the Betts process for refining lead is in operation at Trail, British Columbia, the daily production amounting to seven tons of lead. The crude lead is used as anode in a bath of lead fluosilicate and fluosilicic acid; there are 22 anodes per vat, through which 4,000 amperes are passed, and the pure metal is deposited on the cathode, leaving the impurities, including the precious metals and copper, on the anode in a skeleton of spongy lead.

In a quite different direction electricity is being used for the purification of the water supply of towns. There are two installations of this kind in Germany—Schierstein and Paderborn—where the Siemens ozonising tubes are in use; air is charged with ozone by means of these, and is passed up dripping towers, down which the water trickles, with the result that it is completely sterilised as regards all deleterious organisms. At Schierstein the capacity of the plant is nearly 50,000 gallons per hour, and the power

Digitized by Google

required is 50 h.p., of which, however, only 27 h.p. is used for ozonising; the remainder serves for pumping, etc. The pressure used is 8,000 volts. The working cost is in all from 3½d. to 4½d. per 1,000 gallons. By the Jaruti process water is electrolysed to give pure hydrogen and oxygen, consuming 115 kilowatt-hours per 1,000 cubic feet. A solution of caustic soda is used, with a perforated iron diaphragm to separate the gases. At Stangfjorden, in Sweden, the Jebsen system is used for the manufacture of briquettes from peat. The latter is carbonised by heating with the electric current, derived from water power, and the tarry by-products are recovered. The production of nitric acid from the atmosphere has long been the subject of experimental research; it is now in active operation at Niagara Falls, where by means of electric discharges at extremely high pressures and frequencies the nitrogen and oxygen are caused to combine. The same subject has been dealt with on the Continent, where a return of 52 grm. to 55 grm. of nitric acid per kilowatt-hour has been obtained, using a current of 0·05 ampere at 50,000 volts and 6,000 to 10,000 cycles per second. As Sir William Crookes has shown, the fixation of atmospheric nitrogen may in the distant future have a most important bearing upon the existence of the vast population of the earth, when natural sources fail to furnish an adequate supply of food.

In connection with this subject, the synthesis of sugars by the electrolysis of carbonic acid, ammonium, phosphate, etc., which has been accomplished by Walther, is of no little interest. The extraordinary potency of electrolysis and the electric furnace in chemical and metallurgical processes has been most largely made use of in America, which is, in fact, the electro-chemical headquarters of the world. The various works which derive their power from Niagara Falls are producing caustic soda, chloride of lime, carbide of calcium, chlorate of potash, sodium and sodium peroxide, sodium cyanide, baryta, phosphorus, nitric acid, lead, carborundum, graphite, corundum, etc. A single American concern is producing 4,500 tons of aluminium per annum, while the United States produces 278,860 tons of electrolytic copper per annum, no less than 86·5 per cent. of the world's output. Siloxicon, a highly refractory compound of silicon, carbon, and oxygen, is one of the latest products of Niagara. The electrolytic rectifier, which depends upon the peculiar properties of aluminium in an electrolytic cell, is a device which will have many applications, especially since it has been so arranged as to ingeniously utilise both positive and negative waves of an alternating current.

One of the most important branches of electro-chemistry is that which relates to secondary batteries, and in spite of the immense amount of work which has been done in this direction in the past, remarkable progress has been made of late. The most notable invention in this department is the Edison nickel-iron cell, which appears to be on the verge of adoption on a commercial scale. Elaborate machinery has been designed and constructed at great cost for the rapid manufacture of the cells, and trial cells have been in the hands of European experts for many months, while complete sets have been exhaustively tested in America and England. There seems to be no question that the cells have fulfilled the claims made for them, and that their introduction in quantity will give an immense impetus to the electric automobile industry, and even to accumulator traction in general. The cleanliness, capacity, and seeming indestructibility of the cells, joined to their highly perfected mechanical construction, render them admirably adapted to automobilism, and the stated ability to charge them with 75 per cent. of their full capacity in one hour is a feature of the first importance. Other cells have been brought forward, notably the Elieson cell, which is an improved lead plate cell, with the property of enduring remarkably high rates of charge and discharge without injury, and the "N.S." (Niblett solid) cell, in which the whole of the positive and negative elements are packed tightly in a container. Each of these has meritorious features, but whether they will stand the test of time cannot yet be decided. Besides the foregoing examples, a vast amount of work is being done in every branch of electro-chemistry, and the recent formation of the Faraday Society, admirably named, to further the interests of the science and industry in this country—long after the birth of similar societies abroad, it is true—can well be included as one of the most important and fruitful "recent developments" in the electrical world.

I will now bring this address to a close, as I began it, with a reference to the growth of this Institution. In my opening remarks I omitted an observation which I should have made concerning this growth, and that was in reference to the source from which our members are drawn. Had not a great wave of educational fervour passed over this country some 20 years ago, had not the establishment of technical institutes all over the country taken place, had not Lord Kelvin and others educated their pupils in a way which best fitted them for the position of efficient teachers in these technical colleges, our Institution would not have attained its present importance, and the posts filled by many of its members would, perforce, have been filled by the better educated foreigner. It is a great advantage to the taught that their teachers should be concerned with the practical side of the subject they treat, and this in itself is a justification for those who teach being members of our Institution and taking an active part in its management. Teaching from text-books which are written on an undeveloped science causes the student to learn many things that he has to unlearn, and launches him into the world full of information which may have been abandoned altogether, or is at least five or six years old. If the teachers are in touch with everyday practice the taught profit immensely, and leave their colleges with knowledge which, although it may later require modifying, has at any rate the advantage of being the knowledge of the day. I believe the electrical industry in this country is almost entirely in the hands of electrical engineers educated in England. Can this be said of the chemical industry? I doubt it, and presume that it is because the latter is a much older science, and has not been favoured in possessing in this country so many educational advantages as are offered to those engaged in the electrical industry. It certainly has not, as a general body, had teachers with the same practical experience, although there are undoubted signs that the younger generation is being better taught. To cite one instance in my personal knowledge, out of the many which might be selected: I remember my father introducing into Scotland, for the purposes of calico printing and dyeing, the use of certain coal-tar dyes, the employment of which had just been practicable by Mr. W. H. Perkin. Forty-five years have elapsed since then, and although Great Britain has practically been the home of the raw material and one of the greatest consumers of these products, yet, through the application of greater knowledge and skill, Germany to-day furnishes our printers and dyers with the greater proportion of their requirements. We are being beaten in a race in which the foreigner is handicapped. Is this due to the natural incapacity of the Englishman, or is it due to the want of the opportunities which his foreign competitor possesses? Despite the opinion recently expressed by Prof. Karl Pearson, I like to accept the latter explanation, although, given the opportunities, we must always bear in mind that a chemist's work is laborious in the extreme, and this may not, as a rule, satisfy the ordinary class of English student. In adopting this illustration I do not wish to be misunderstood. I have no intention of implying, and it would be foolish to imply, that this country does not possess chemical knowledge of the very highest order, as witness the number of distinguished men whom we know by name, and the work they have done, and also the large number of chemical works established in the London, Manchester, Glasgow, and other districts. I also fully recognise that the chemical industry cannot be fairly compared with the electrical industry, as it occupies a much wider field, and is a much more difficult subject to master. I use the illustration as I do not believe the mass of the people engaged in the industry have placed at their disposal sufficient opportunity for proper instruction, or for acquiring knowledge, as is the case in Germany and some other countries.

With wisdom, we in this country open our arms to the skilled man of other countries, and through his skill we can, in certain directions, maintain supremacy in some of our productions. The pity of it is that we have not

Digitized by Google

amongst our own countrymen men of equal education and skill. One may say that the electrical industry is also suffering, and that the signs of it are the large importation of American and German machinery into this country at the present time; but I venture to disagree. Americans and Germans are doubtless appearing on our markets, and in many cases owing to greater skill in manufacture; but the financial side of the question has a great deal to do with their incursion, and especially is this so with their competition in our colonies and in non-manufacturing countries. We must, as a policy, continue to welcome all comers, but while so doing we should equip ourselves so that by sheer skill and ability we may conquer in the end. The equipment we require is, everyone now admits, technical education, and thus we are developing in all directions. The electrical engineers as a class are better equipped than any other class I know of, thanks to the teaching received in our technical institutions from very capable men, some of whom we are proud to see numbered among the past-presidents of this Institution.

During the recess, several powerful advocacies for the furnishing of greater educational facilities to the students of this country have been published, and it is gratifying to see that these publications were made in a manner to bring them before everyone who cares to read them. Sir Norman Lockyer, in his presidential address to the British Association meeting at Stockport, made a stirring appeal, which must sink into the soul of every thinking man who has the welfare of his country at heart. Sir William Abney, as chairman of Section L—educational science—placed before the public what has been done since 1853 by the Science and Art Department with the small amount of funds at their disposal. Prof. Meldola's lecture, delivered in August last at Oxford on chemical industry and research, should also be mentioned, as it deserves careful reading. Opportunely Prof. H. E. Armstrong has just had published by Macmillan and Co. a collection of his writings on education. Sir William Ramsay, the president of the Society of Chemical Industry, and many others who are interested in industrial development, are actively forwarding the cause, and it is to be hoped that some good may be evolved from the atmosphere of public interest which has been created, and that we may thus eventually find the men of this country as well furnished as their foreign competitors with the necessary knowledge, and with the means of applying it in investigation. Our past-president, Dr. John Perry, informs me that there is under consideration the formation of a science guild, whose fundamental object will be the encouragement of the application of scientific principles to industrial and general purposes. We must all hope those engaged in the matter will succeed in founding this guild, as there doubtless exists a blank which it can fill. I am glad to see some of our members—notably my predecessor, Mr. Swinburne, and our honorary member and past-president, Mr. Swan—are interesting themselves in the formation of the Electro-Chemical Society, to which I have already referred, and I am sure we all wish them every success in their effort to specialise in Great Britain this very important subject.

For the future development of the usefulness of the Institution there appears to me to be one matter worthy of our utmost attention. The Institution membership extends all over England and the Colonies, and we have found it a useful addition to our constitution to establish local sections in different centres. Since these sections have been formed, many valuable contributions have been incorporated in the *Journal* of the Institution which might not have appeared there had the opportunity of having a meeting place in the author's neighbourhood been absent, and had there not existed an organised assembly to discuss the subject submitted by him. The local sections are growing, and must by the nature of things increase in importance. The development of the electrical industry in the provinces must advance with greater strides than in London, where manufacturers are hampered by high local rates, and sometimes obstructive legislation, which appears to be a necessity in our large metropolis, and which is, fortunately, not so essential in smaller communities. Again, in the neighbourhood of London the cost of raw material is appreciably higher; fuel is also higher, and the charges for the transport of the finished goods to their destination handicaps the London manufacturer. These, in addition to the higher scale of wages paid, are fast driving manufacturers into the provinces. Such a migration, from a general point of view, is, perhaps, advantageous, but it indirectly affects the Institution in a way which is not of advantage to the central body. If the migration continues to the same extent as took place in the case of London shipbuilding many years ago, the centre of production, so to speak, of the electrical industry will gradually gravitate northwards, and nothing but consumers will be left in the Metropolis. Many of our ablest members are already in the provinces, and it is quite a question for the Institution to consider whether the day is not fast approaching when we should extend our system of decentralisation. Is it not time that we should consider the establishing of a local section in London, similar in all respects to the local sections we have in Birmingham, Dublin, Glasgow, Leeds, Manchester, and Newcastle? In this new local section papers affecting London could be read, and be published or not in the *Journal* of the Institution in the same manner as papers in the other local sections are dealt with. London would continue to be the headquarters of the Institution, and Institution meetings could be held, say, four times a year. At these papers of general interest could be contributed. If any such scheme as this were adopted, the constitution of the Council of the Institution would be somewhat affected. The chairman and committee of the London Local Section would, of course, be all London men, but the Institution would have a larger field from which to select its President and Council, as men who have their business in the provinces, and who cannot spare the time to attend the present numerous Council and Institution meetings, might be able to attend the less numerous meetings which would be the outcome of some such rearrangement.

In conclusion, I must thank you for the kind tolerance with which you have received the remarks that I have had the pleasure of submitting for your acceptance.

A NEW COMPOUNDED THREE-PHASE GENERATOR.*

The more recent three-phase generators with the Heyland compounding winding built by Messrs. Kolben and Co, have been of the rotating radial pole magnet type. They are excited by means of a small commutator connected to the magnet winding in a similar manner to the original Heyland asynchronous generators, and the compounding under all conditions of load and power factor has been found to be extremely satisfactory. The main current generated is led directly round the magnets by means of the commutator exactly as in continuous-current compound generators. The commutator performs two distinct operations. It rectifies the main current into a uni-directional current, and also splits it up into its two components—power current and wattless current—and feeds these to the magnets in such a way that the compounding effect is practically proportional to the wattless component. The chief characteristic of the machine is the commutator. Sparkless running is, of course, of the first importance, and this is attained by an interesting arrangement explained below, and higher commutator voltages can safely be employed than were permissible in the case of the asynchronous machines. In spite of the comparatively high brush voltage, the small size of the commutator, and the fewness of the segments, the working is as satisfactory as in the best continuous-current machines.

It is well known that, in order to regulate synchronous alternators for constant voltage, the excitation must vary practically with the wattless component of the current, so that the commutator in these machines is distinguished from that in the asynchronous machines by the fact that it must pass only this component round the magnet winding. As, however, the arrangements for compounding are similar in the two types of machines, and in order to

* Translation of an article by E. Kolben in *Elektrotechnische Zeitschrift* for Oct. 8, 1903.

Digitized by Google

point out the advantages of the newer type, it will be well to give a short description of the asynchronous machine first. Consider an asynchronous machine simply arranged for self-excitation, but not for compounding. The action can be followed by means of Figs. 1 and 2. Fig. 1 is a development of the rotor which is supposed to have a two-phase winding, slots 1, 1, 1 being the slots per pole of one phase and 2, 2, 2 those of the second phase. The instantaneous position of the poles is shown at N and S S—*i.e.*, phase 2 lies in the centre of the pole, so that the field must be produced by the current in phase 1, and the whole magnetising current must, therefore, be supplied to phase 1.

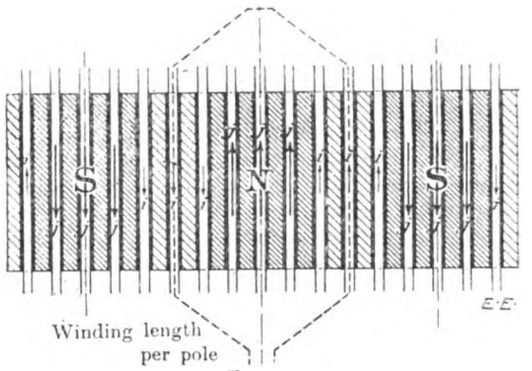

FIG. 1.

If a non-inductive load is now taken from the machine, the stator currents will divide at the pole centre—*i.e.*, they will be opposite to phase 2 of the rotor—and in consequence of the slip of the rotor field produced by the load, currents, J, will be induced in phase 2 of the rotor, and these currents will be equal and opposite to the stator currents.

It will be seen from Fig. 1 that the winding space is employed to the best possible advantage, half the winding (phase 1) carrying the magnetising current and the other half (phase 2) the power current. If the load taken from the synchronous machine is inductive, on the other hand (Fig. 2), the stator current will no longer flow at the middle of the pole, but at a point 90deg. in phase from it—*i.e.*, it will flow in those stator conductors which are opposite to phase 1. In order to counteract the armature reaction, the exciting current in phase 1 must be increased by an amount equal and opposite to J. No current

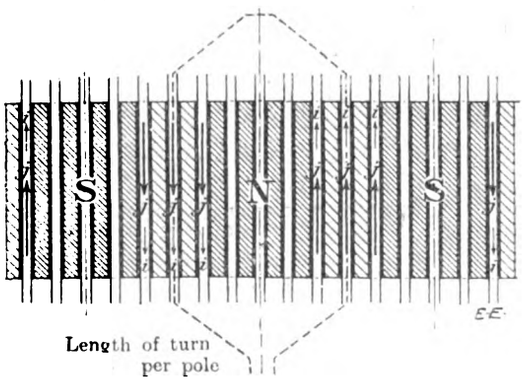

FIG. 2.

due to slip will be induced, however, so that phase 2 will carry no current. The whole rotor current, power current, as well as magnetising current must, therefore, be supplied by phase 1 alone, thus making the current division and the employment of the winding space the worst possible. This is one reason why the asynchronous machines were better suited for non-inductive loads than for inductive ones. It is obvious that if a given machine were excited by a continuous current half of the copper might be omitted, since phase 2 would carry no current on inductive load, and so would be superfluous. A purely wattless load is, however, only a limiting condition which is never quite attained in practice. On the whole, however, it is evident that the advantages of the asynchronous machine fall off as the wattless currents increase.

In order to consider the effect of replacing the asynchronous rotor (Fig. 2) by a suitably arranged ring of projecting poles, the total flux per pole, the air-gap, and the ampere-turns of the machine may be assumed to be practically alike in the two cases. Supposing the machine had six slots per pole, the iron section of each field pole would correspond to that of four teeth. Phase 2 is omitted, and the four neighbouring teeth may be combined into a single polar projection. This results in a ring of poles as shown developed in Fig. 3. Circular poles are chosen, as they are well suited for the proportions mentioned, and permit of a very decided reduction in the average length of turn per pole. With the dimensions chosen this length will hardly equal half its previous value. Supposing that the copper section per pole remains unchanged, the weight of copper, owing to the omission of phase 2 and the halving of the mean length, would be reduced to one-quarter and the copper loss in the rotor to one-half the previous values. These

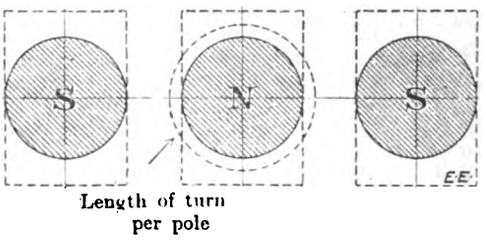

FIG. 3.

results are, however, rather too favourable, as no allowance has been made for the greater leakage which occurs in synchronous machines, and which would necessitate a slightly greater core section, length of turn, and number of ampere-turns. Still, it is always possible to reduce the rotor copper and rotor losses by at least half, as compared with the compounded asynchronous machine. This reduction relatively to the compounded asynchronous machine, is attained by the omission of phase 2 and the good use of the winding space. Relatively to ordinary synchronous machines, a saving is also attainable due to the compounding permitting smaller air-gaps, weaker fields, and greater armature reactions to be employed.

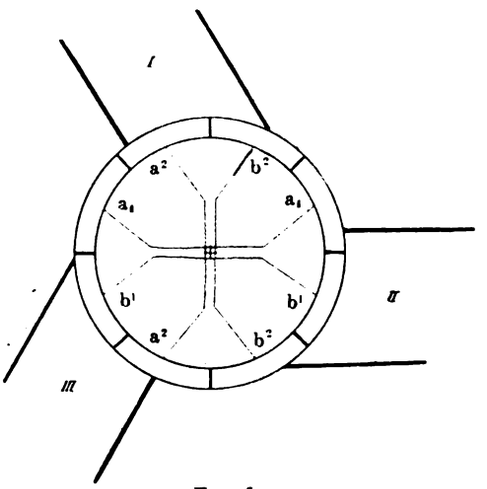

FIG. 4.

In order to explain the method of compounding these new machines, reference once more to the arrangements of the asynchronous machines will be of use. Fig. 4 shows the connections of a two-pole asynchronous machine with a two-phase rotor. The separate phases in the recent constructions consist of wires wound in parallel, in order to avoid sparking of the commutator by preventing the occurrence of appreciable magnetic leakage between them. The main current of the machine is delivered to the separate phases either at right angles to or in the same direction as the field, according as the current in the stator is power current or wattless current. In this case, for instance, in accordance with Figs. 1 and 2, phase 1 carries the wattless component and phase 2 the power component of the current at the instant shown.

(To be continued.)

NOTES.

De Forest Wireless Experiments.—Mr. De Forest has commenced his experiments in this country under the auspices of the Post Office. They are being carried out between Howth in Ireland and Holyhead, and are reported to have so far given successful results. Messages are sent at the rate of 25 to 35 words a minute. It is stated that although there is a Marconi station at Holyhead about three miles from the De Forest station, no interference with or disturbance of the messages sent to and from Howth was noticed.

West Indian Cable Breakdown.—The West India Committee has addressed a letter to the Colonial Secretary on the subject of the constant breakdowns of the telegraphic communication with and between the British West Indian Colonies. In it they say that in the last four or five months the situation has become aggravated. On no less than five occasions during the present year the Trinidad-Demerara cable has broken down, and it is unnecessary to emphasise the serious inconvenience and loss which has thereby been incurred.

Tramways and Light Railways Association.—The members of this association and those to whom invitations have been issued will meet on Dec. 11 to hear an address by Mr. Atherley-Jones, K.C., M.P., the president of the association, on "Fiscal Policy in Special Relation to the Tramway and Light Railway Industry." Sir C. Rivers Wilson, G.C.M.G., the past-president, will take the chair at eight o'clock at the Society of Arts, John-street, Adelphi, and a discussion and vote will follow, in which several well-known gentlemen in engineering and commercial circles are expected to take part.

Obituary.—We regret to hear of the death of Colonel F. Pescetto, the local hon. secretary of the Institution of Electrical Engineers in Italy. The deceased gentleman was a prominent figure during the Italian visit last summer, and he earned the gratitude of every individual member of the party for the exceeding kindness and courtesy he displayed on that occasion. Mr. R. Kaye Gray at the last meeting of the Institution made a sympathetic reference to the late colonel, describing him as an "exceedingly kind-hearted and gentle man." In his profession Colonel Pescetto was director of the electric works at Genoa.

Yorkshire College.—A determined effort is being made to convert this institution into a university. The only difficulty in the way is the raising of the necessary funds. The Lords of the Committee of the Privy Council have had the matter under consideration, and they have agreed to recommend the grant of a charter on the understanding that the West Riding County Council makes a substantial subvention towards the university, and that the promoters undertake to raise a capital sum of at least £100,000 by the earliest possible date. There seems to be some difficulty in deciding on the name which the new institution shall bear, but doubtless this will not be allowed to stand in the way of the ultimate consummation of the scheme.

St. Louis World's Fair.—A profusely illustrated and informing handbook has been issued by the St. Louis Gottsschalk Printing Company giving a general and concise description of the arrangements for the St. Louis World's Fair to be held in 1904. Mr. Chas. M. Kurtz, Ph.D., assistant chief in the department of art, is responsible for the compilation of the book, and he is to be congratulated both on its excellent get up and the general usefulness of the information which it contains. In the section devoted to this country we find it stated that the British Government will erect a pavilion, the main hall and the principal front of which will be modelled after the orangery, or banqueting hall, of Kensington Palace. Beyond the banqueting hall will be an inner court ornamented with fountains and statuary.

The Engineers' Club. — Under this title a new association has been formed for the promotion of social intercourse between members of the engineering and allied professions. A smoking concert was held at the Westminster Palace Hotel on Friday last, and the programme at present arranged includes a children's party, followed by a cinderella dance, at the Caxton Hall, Westminster, on Saturday, Dec. 12. An attractive list of other social gatherings to follow is being gathered. The club has been founded under the auspices of the Junior Institution of Engineers, but membership is open to the profession generally upon proper introduction. It is hoped in the future to be able to engage permanent rooms, so that members may enjoy the usual advantages of a clubhouse. Mr. Fred. S. Pilling, 20, Victoria-street, Westminster, S.W., one of the joint hon. secretaries, will be pleased to answer any enquiries.

The Osmium Lamp.—Dr. W. Wedding, professor of the Technical College, Berlin, has made a report on some tests he has carried out in order to determine the life and economy of the osmium lamp. In the experiments two groups, consisting of six 37-volt lamps each, were connected in series across a 220-volt circuit. In group 1, for the first 3,132 hours the average life of the six lamps was 2,853 hours, and the average candle-power fell from 30·1 to 23·7. The mean consumption per candle-power rose from 1·46 to 1·78. After 520 hours the first lamp collapsed, and after 3,724 and 3,940 hours respectively two others gave out, the remaining three still burning after 3,973 hours. In group 2, which consisted of six 25-c.p. lamps, the report gives the average life as 1,479 hours, the candle-power dropping in 2,198 hours from 25·1 to 19 9, and the energy consumption increasing from 1·37 to 1·75 watts per candle-power. These excellent results give ground for hope that lamps of this character may be turned out before long in commercial quantities and at commercial prices.

Technical Education in London.—The Technical Education Board for the county of London have prepared a report showing the growth of technical education so far as it is connected with the five schools and institutions managed by the Council. The total number of students attending the classes at these schools was 2,053 at the end of October last, compared with 1,633 in 1902—an increase of 420. Improvers, learners, and apprentices under 21 years of age are admitted to the classes free, whereas other students pay 10s. per session, with the exception of artisans or working women earning less than 30s. a week, who pay 4s. 6d. per session. It is gratifying to notice that at each school the free students attend for a larger number of hours than the paying students, and the percentage of those who make over 20 hours' attendance per session is in each institution greater in the case of the free students. The American Ambassador has consented to present certificates to the county scholars, and the presentation will take place on Jan. 29 at the Queen's Hall. It has been arranged to hold the annual conference of teachers at the South-Western Polytechnic from Jan. 7 to 9, further particulars of which will be published in due course.

New Books.—Messrs. Whittaker and Co. will publish shortly "Electric Traction: A Practical Handbook on the Application of Electricity as a Locomotive Power," by Mr. John H. Rider, chief electrical engineer to the London

Digitized by Google

County Council tramways. The work will deal with the various systems of construction of, and the apparatus, generating plant, etc., used in, electric railways and tramways.—"Directory and Map of Automobile Charging Stations" (The "Electrical Times," Limited. Leather, 3s. 6d.; cloth, 2s. 6d.). The directory contains particulars of upwards of 700 places in the United Kingdom where the batteries of electrically-propelled automobiles and the ignition accumulators of petrol-driven cars may be recharged, the information given including such useful details as the hours of business, the current available, price charged, and whether repairs can be carried out and garage given. The map shows clearly all the main roads, while all the places mentioned in the directory are marked in various ways according to the nature of the facilities offered. The work is of special value in the case of electric vehicles, for it is easy with the aid of the map and directory to plan out a tour and be certain of obtaining facilities for charging *en route*.

Railway Electrification.—It will be remembered that in the abstract we gave in our last issue of a long article under this title appearing in the *Times*, the hint was thrown out that if electric supply companies in London were in a position to provide the necessary electrical energy, the question of converting the suburban steam railways to electrical working would be very much simplified. Mr. R. Stewart Bain, the managing director of the London Electric Supply Corporation, has written a letter to our contemporary, in which he states that in about a month's time his corporation will be in a position to supply electrical power on a large scale for traction purposes similar to those described in the article. The Deptford power station of this corporation, one of the largest electric generating stations in the country, is situated in close proximity to three of the southern railways, and from that station it would be possible to obtain a supply of electric power to work the suburban traffic of any or all of these railways at a price less (owing to the variety and extent of the load at the station) than it could be produced by the railway companies separately or jointly. The saving effected in capital expenditure to the latter from such an arrange ment is obvious.

The Ramsgate Dilemma.—The Ramsgate Corporation have been much exercised for the past fortnight on the question of electric lighting. The Isle of Thanet Light Railways Company and the Ramsgate and District Electric Lighting Company are both applying to the Board of Trade for electric lighting provisional orders, and both have applied to the Corporation for their consent. It greatly grieved the members of the Corporation that they were not allowed to have both schemes, but they were informed by the Board of Trade that competing orders would not be granted. From the information we have received, the light railways company offered the more favourable terms for private supply, and the electric lighting company the better proposals as to purchase. We presume that it is due to this latter consideration that consent has been granted to the application of the electric lighting company. Without more detailed information, however, it is useless to criticise the decision of the Corporation, and we would only say that it seems a pity to multiply electric supply undertakings in one district. The light railway company have their works in full swing, and could with their better load factor give economically the cheaper supply promised.

Institution of Electrical Engineers.—The next meeting of the Institution in London on Thursday, the 10th inst., falls on the three hundredth anniversary of the death of William Gilbert, and the Council have decided to mark the occasion by a fitting ceremonial. The Mayor and other representatives of the borough of Colchester will attend officially at 8 p.m. to receive an historical picture (representing Dr. Gilbert in the act of showing his electrical experiments to Queen Elizabeth and her Court), which will then be presented by the Institution to the borough of Colchester, in which town Gilbert was born in 1544, and died in 1603. At the conclusion of the presentation an ordinary general meeting will be held, at which the following paper will be read: "The Slow Registration of Rapid Phenomena by Strobographic Methods: The 'Ondographe' and 'Puissancegraphe' (Wave Recorder and Power Recorder)," by E Hospitalier, president of the Société Internationale des Electriciens. M. Hospitalier will also give a demonstration of the ondographs. If time permit, the following paper will then be read: "On the Magnetic Dispersion in Induction Motors, and its Influence on the Design of these Machines," by Dr. Hans Behn Eschenburg. We would remind our readers that the annual dinner takes place the night before at the Hotel Cecil.

Electric Discharges in Gases.—The current number of the *Journal* of the Chemical Society gives a short abstract of a paper by Mr. W. R. Carr on the laws governing electric discharges in gases at low pressures. Paschen has found that with spherical electrodes and a given spark potential the gaseous pressure at which an electric discharge occurs is inversely proportional to the distance between the electrodes. The author, using parallel plate electrodes in a uniform field, extends the application of the above law to a number of gases (air, hydrogen, and carbon dioxide) for pressures at, and below, the critical pressure (this being the pressure for which the spark potential has its minimum value). The values of the spark potentials were for all pressures, independent (1) of the size of the electrodes, provided the discharge took place in a uniform field; (2) of the material of the electrodes, iron, zinc, aluminium, and brass being used in turn. Paschen's law appears to be applicable so long as the distance between the electrodes is greater than the diameter of the sphere of molecular action. The minimum spark potential varies with different gases, but is a constant for a given gas, independent alike of the gaseous pressure and of the distance between the electrodes. From the author's results it seems that the minimum spark potential is a property of the atom rather than of the molecule; for any selected gas its value may be calculated additively.

Noise of Electric Tramcars.—In a leading article a few days ago the *Times* called in question the noise made by the running of electric tramcars. We know that in some cases this trouble has positively amounted to a nuisance, which frontagers on the line of route have been powerless to prevent. It is usually during the first months of operation only, however, that complaints are made on the score of noise, as witness the case of the electric cars in West London. Mr. J. Williams-Benn has written to our contemporary inviting its leader writer to take a trip on one of the London County Council electric cars and, by practical illustration, be convinced of the error he has fallen into by assuming that trams run on the conduit system are equal offenders with cars driven by the overhead trolley in respect of noise. Mr. Benn says he will discover that the conduit system is much quieter than the overhead. In the latter case there is the grinding of the rails plus the noise of the trolley wire. Indeed, the noise of the conduit system, as now running, does not compare unfavourably with the rumble of the horse cars—*i.e.*, if the clatter of the horses' hoofs be taken into account. As to the "nuisance" to the district, Mr. Benn says the fact remains that all the boroughs in

Digitized by Google

the south are clamouring for an extension of this "nuisance" at the earliest moment. The letter concludes: "So far as our information goes, property has perceptibly appreciated. It is difficult to understand why a beautiful and clean electric car should depreciate property more than a lumbering and dirty horse car. Anyway, our experience is that north and south the people 'want more' London County Council electric trams on the conduit system."

Rugby Engineering Society.—This is the title of a new society which has established itself in the Midlands. The scheme was promoted by the Rugby staffs of the British Thomson-Houston Company and of Messrs. Willans and Robinson, Limited, but anyone interested in engineering is eligible for membership. The society already numbers some 350 members, and has as its first president, Mr. W. J. Larke, and as vice-presidents, Messrs. C. H. Wingfield and F. Samuelson. The two hon. secretaries are Mr. E. R. Briggs and Mr. C. C. Wharton respectively. The first ordinary meeting was held on Thursday evening, Nov. 5, when an interesting paper was read by Mr. F. Samuelson on the "Curtis Steam-Turbine," the paper being illustrated by half-size sectional drawings of a 500-kw. turbo-generator running in the British Thomson-Houston power-house at Rugby, as well as by curves showing the steam consumption, etc. The paper itself is a most interesting one, and gives clearly the principles involved in the Curtis steam-turbine. A great point is made of the fact that the steam consumption per kilowatt-hour is wonderfully uniform over a wide range of load. The reason for this is that the turbine is of the impact type, and the governing over a range of load is effected by varying the number of nozzles actually in use. We hope to give a full extract from the trial figures in this paper at an early date. The second meeting on the 19th ult. was devoted to a continuation of a discussion on the paper, and a very complete reply was given by Mr. Samuelson. The third meeting was held yesterday, when a paper was read by Mr. D. P. Thomson on "The Central London Railway."

Electric Motors at Hackney.—Mr. L. L. Robinson, the electrical engineer to the metropolitan borough of Hackney, has just issued an interesting pamphlet on the application of electric motors to commercial purposes. The object of the publication is to increase the demand for electric power, which has already reached considerable dimensions in the borough. Although the supply of electricity was only commenced at the end of October, 1901, there are now 147 motors connected to the mains with an aggregate horse-power of 537. The information given in the pamphlet is interesting from many points of view, and the consumer will specially value the figures given on p. 17 of the average quarterly accounts with various classes of consumers. These are worked out as the average cost per brake horse-power per quarter, and come surprisingly low in a number of instances. Thus, one firm using electric motors for an engineering workshop with lathes, circular saws, etc., finds the average cost only £1 per horse-power per quarter, or £4 per annum. Ore-crushing plant, working longer hours, of course, costs more, and it is likely that this plant uses more regularly the rated output of the motors. The charge for electrical energy in Hackney used for driving motors has been reduced from Oct. 1 last to the following rates: 2d. per unit for all consumption up to 1,000 units per quarter, and 1½d. per unit for all electrical energy used in excess of this quantity. As the Council have not the powers to let motors out on hire, they have entered into an arrangement with the Rhodes Electrical Manufacturing Company to do this for them. The terms set forth on p. 23 give the rates charged under this hire-purchase system on one, two, or three year leases. The quarterly payments in this case include interest and repayment of capital. These terms will be of service to small users, but many firms will prefer to buy their equipment outright after reading the results that have been obtained elsewhere in Hackney. The illustrations in the pamphlet leave nothing to be desired, and show a great variety of application of electric motors.

High-Voltage Direct-Current Traction.—At a time when the application of high-voltage alternating current to traction work is being widely discussed, it is interesting to hear of an experiment which Mr. R. Thury, of Geneva, is carrying out in Southern France with a trolley system taking continuous current at 1,200 volts. The line in question extends between St. Georges de Commiers and La Mure, about 20 miles apart, near Grenoble. The main business appears to be freight, and one locomotive is in service at the present time. It weighs about 50 tons, and is of 500 h.p. capacity, there being, in fact, four motors of 125 h.p. capacity each, two on each truck. These are connected in series, and each require 185 amperes at 625 volts. The line is equipped on the three-wire system, so that the voltage between the outside wires is 2,400 volts. The road is a grade with slight slope, and the loaded train comes down with the motors arranged to run as generators and act as brakes, being connected to the resistances. For breaking the circuits, oil switches are used. Hauling 20 cars of a gross weight of 111 tons, the locomotive makes a speed of about 22 km. per hour on the 2¾ per cent. grades. The overhead construction is solid, with double contact wires and double sets of Siemens sliding bow contacts, exerting the slight upward pressure of 4½lb. The overhead line consists of two "figure 8" copper wires, 114mm. cross-section, in span on wooden poles. As already stated, the voltage is 2,400 volts between the outside wires, and 1,200 volts between each contact wire and the rail forming the neutral. The resistances employed in association with the controllers are carried in the motorman's cabin, being large enough to absorb easily the electric braking current produced by the locomotive on the descent when the motors are run as generators. The locomotive has also a hand braking system and an air system, for which the compressor is driven by a small motor of 4 h.p. at 1,200 volts. Special care has been taken with insulation in view of the high voltage used. We are indebted for the above particulars to the *Electrical World*.

Conductor Rail Steels.—Before the American Institute of Mining Engineers last month Mr. J. A. Capp read a paper in which he gave the results of tests made with the object of drafting an original specification for third-rail steel. Steels of as wide a range of composition as could be obtained were tested, and the results are given in various tables and diagrams. The T-section rail is the outcome of designs intended to present the greatest life and strength of the section with the least weight of the metal, but, on the other hand, one of the chief requirements of the third rail is an ample cross-section to carry the current without an undue drop in potential. The strength of the section is of little moment. Bearing this in mind, a section of a conductor rail has been designed by Mr. W. B. Potter which, when 2·5in. wide by 4in. high, will weigh about 98lb. to the yard. A dovetail at the bottom provides an easy means of securing the rails by fishplates of special form, and any of the common forms of bond may easily be applied. From the tests carried out by Mr. Capp on the influence of special additions to steel upon its electric conductivity, it appears that manganese preponderates in influencing the resistance of the steel, and that for lowest resistance manganese must be present in very small quantity, much smaller than is usual in merchant

Digitized by Google

steel or structural steel. While all the usual impurities found in steel reduce this conductivity, so great is the preponderance in the influence of manganese that other elements may be tolerated in quantities which the steel-makers would consider reasonable, without unduly increasing the resistance. For a satisfactory third rail the lowest possible resistance, say from 6 to 6·5 times of copper, is not necessary. Assuming, then, that a rail made from steel having a resistance not greater than eight times that of copper is desirable, the specified analysis of maximum impurities allowable should be: carbon, 0·15 per cent.; manganese, 0·30 per cent.; phosphorus, 0·06 per cent.; sulphur, 0·06 per cent.; and silicon, 0·05 per cent. It appears that the wear and tear question is a very serious one. From the remarks with which the author concluded his paper, it seems that the wear and tear on the third rail of the Manhattan Railroad has reduced it by about $\frac{1}{10}$in. since the time of its installation.

The Royal Society.—The anniversary meeting of this society was held at Burlington House on Monday afternoon, when there was a large attendance of Fellows. A feature of the meeting was the presentation of the medals in the gift of the society. Among the recipients was M. Pirre Curie, who received the Davy medal "for the most important discovery of the year in chemistry." The discoverer of radium was accorded a most sympathetic reception. The Hughes medal was awarded to Prof. Johann Wilhelm Hittorf for his experimental researches on the electric discharge in liquids and gases, extending over a period of more than half a century into the present year. An incident of the proceedings was the formal presentation of a subscription portrait of Lord Rayleigh, painted by Sir George Reid. The president mentioned that though one of the more immediate objects of those who conceived the idea of a portrait was to commemorate the distinguished scientist's great services in connection with the foundation and administration of the National Physical Laboratory, it was also intended to mark his secretaryship of the society for 11 years and his labours on several scientific commissions. He further referred to Lord Rayleigh as one of the most eminent original workers of his generation, who had traversed the whole range of physical science, bringing to light its essential principles. Considerable division of opinion was manifested in regard to a successor to Sir Michael Foster, M.P., so long one of the secretaries of the society. The nomination of the council, however, was confirmed by ballot, and Sir Archibald Geikie was declared elected. In the course of his address Sir Wm. Huggins, the president, referred to the loss sustained by the society in the death of Sir Geo. Stokes, to whom, he mentioned, a memorial is about to be erected in Westminster Abbey. An important suggestion made by the president was for the better inter-communication of ideas between the various learned societies in the kingdom, and that the Royal Society's papers should be more speedily published. In the evening a banquet was held in the Whitehall Rooms, at which the president was supported by a large and distinguished company.

Etiquette for Electrical Contractors. — The members of the London Electrical Contractors' Association at their meeting on Tuesday evening were asked to discuss the question "Are we tradesmen?" and some of them did so in no uncertain manner. Mr. J. B. Joseph, who introduced the subject with a short paper, declared that the varied character of the work of electrical contractors entitled them to the dignity of professionals ranking with engineers, and argued that, in keeping with professional etiquette, they ought not to cut their accounts or allow discounts for electrical fittings or to consulting engineers. This led to a fairly spirited debate, and on the first point the meeting was evidently against Mr. Joseph. Mr. Rawlings, for example, bluntly declared that he preferred to be able to buy and sell than to call himself an engineer or a consulting engineer. They were business men—that was the beginning and end of it. Another member (Mr. Bedford) took a similar line, pointing out that professional men were not supposed to advertise. Mr. Rolf, a consulting engineer, argued that this was not a question of professionalism, but a personal matter. He was sure there was nothing in the business of an electrical contractor which would debar him from association with engineers. On the other part of the subject the meeting was certainly with the author in his denunciation of the practice of cutting accounts and allowing discounts, and it was agreed that, in the case of consulting engineers, allowances for professional services ought to be handed direct to them by the principals, and not be included in the contractors' estimates. Another point upon which there was general agreement was that the wiring of a building and the fixings of fittings ought to be carried out by the same contractor, as the contrary practice led to trouble and confusion. A suggestion made by Mr. Rolf, that it should be binding upon all firms who were members of the association not to fix fittings on other contractors' wiring, was rejected as impracticable, but the feeling was expressed that something of the sort ought to be done. We should, perhaps, say that during the debate both Mr. Rolf and Mr. Gaster, another consulting engineer, repudiated any suggestion that consulting engineers received discounts from contractors except such as were provided for in the estimates. We understand that the question of fusion with the Federated Ironmongers' Association is under consideration by this association, having regard to the common interest in electrical fittings of the two trades.

Storage Batteries. — The paper which Mr. W. Hibbert presented to the meeting of the Institution of Electrical Engineers last week, describing experiments conducted by himself on the new Edison secondary or storage battery, has led to an interesting communication being published in the *Times* of the 27th ult. from a correspondent signing himself "Multiple Supply." The object of the communication is to direct attention to a suggested application of Edison's battery outside of the motorcar. In brief, the proposal is that larger batteries of heavier construction than those used for road travelling should be employed as an aid and adjunct to recognised systems of long-distance electrical transmission on railways. In effect, such a system has been devised. The writer thus describes it: An electric locomotive and tender is used, the tender carrying an Edison battery weighing from 15 to 30 tons, according to the speed desired and the weight of the train. If 20 tons of the latest, or 1903, type of Edison battery should be used, then a train weighing 200 tons could be propelled from Victoria to Brighton in 45 minutes or less, or at a speed of 75 miles per hour, by battery power only. In this case, as in all others, the total weight of electric locomotive, tender, and battery would be from 10 to 15 per cent. less than that of a steam locomotive and tender able to do equal service. But as batteries take time to charge, they would be used only as an aid to other means of propulsion, and in the following manner: Current from suitably located generating stations would be conveyed to all trains by a light third rail, this current being either continuous or alternating as desired. This would be used to drive the train through suitable motors, the extra power required in starting from stations and on upward gradients being supplied by the battery current applied to other motors. If the line supply should fail from any cause, then

Digitized by Google

the batteries alone would be called upon to propel the train to its destination or to a section of line not in difficulties. To ensure economy of construction, the third rail would be omitted at all sidings, in station yards or tunnels, on bridges, or wherever its use would be dangerous to life, battery power only being used at such points. Without going into the elaborate details which have been fully worked out by competent engineers, the writer says that the first cost of such a system is about one-fourth that of anything now in common use, and much less than that of some proposed high-voltage systems, while in security of operation it is superior to the reliable steam locomotive. Indeed, for an expenditure not exceeding £4,000 per mile of single track, trains weighing from 200 to 350 tons may be operated at intervals of from 10 to 15 minutes throughout the greater part of the day, and at a normal speed of 80 miles per hour, thus practically duplicating the train capacity of most railway lines. The question of efficiency and cost of power supplied to the motor is not treated by the writer.

The Late Sir Frederick Bramwell.—We regret to have to record the death of Sir Frederick Bramwell, F.R.S, which took place on Monday last in London. This eminent engineer completed his eighty-fifth year on March 7 last. The story of his life is one of strenuous and successful labour, and is closely bound up in the progress of engineering. He was apprenticed in 1834 to one John Hayne, who was then making steam-driven carriages to run on the roads, and it was only at the latter part of his life that such self-propelled vehicles gained a place in commercial and private life. In was thus in a "steam-locomotion-on-common-roads atmosphere" that Bramwell's apprenticeship was passed, and he made full use of his opportunities to gather facts and information which might afterwards be useful to him. At that time technical education was a thing unknown, and but few engineers could take advantage of such scientific education as was to be obtained. "Innate love of the profession" and "mother wit" were the sole educational aids available to the engineers of that date. Their success was, therefore, "in a large measure due to the fact that they became engineers literally because they could not help it: that the taste for engineering was born with them, and that their very natures compelled them to follow that taste." We quote Sir Frederick Bramwell's own words, and he was in his own person a remarkable exemplification of them. His extensive and varied information was the outcome of personal observation and experience. Study was uncongenial to him, but his retentive memory rarely lost its hold of any detail which he had seen or had described to him, and his mind became a storehouse of professional learning. Of Sir Frederick's work amongst engineering and scientific societies, it suffices to say that he occupied at one time or another the presidential chairs of all our leading institutions. His work for the Institution of Civil Engineers was most highly appreciated, and he inaugurated the benevolent fund which has done so much good amongst old engineers. Electrical engineering has received much attention from him, as instanced by the many electric works for the design which he was responsible. Of these, the pioneer electric lighting station at Derby was an example, and the inauguration ceremony in connection with the South Wales Electrical Power Distribution Company was one of the latest occasions on which Sir Frederick entertained a large audience with engineering reminiscences. He was a brilliant speaker, and his ready wit helped to enforce his arguments in a most pleasant way. Thus the Institution of Electrical Engineers in London enjoyed last session a most entertaining defence by him of our present system of weights and measures as against the decimal system. The engineering profession as a whole is poorer by the loss of Sir Frederick Bramwell, and his genial humour, clear judgment, and ready wit will be missed at the meetings of the many societies he so regularly attended. A memorial service will be held to-day at St. Margaret's Church, Westminster, at 1 o'clock. This service has been arranged by the Institution of Civil Engineers. Members of other scientific societies are invited to be present.

Radium.—Sir Wm. Ramsay's lecture before the London Institution last week on "Radium and the Periodic Law" was perhaps chiefly remarkable for his declaration that the transmutation of elements as a theory was by no means absurd. The lecturer briefly sketched the outline of the periodic law, which is beginning to suggest some root identity between the various elements, and then told of some practical results that had followed the discovery of this law. Sir William traced the various steps which led to the discovery of radium. Mendelieff, the great Russian chemist, ranged the elements—hydrogen, oxygen, carbon, nitrogen, sodium, the metals, and the other substances of which all things were composed—in the order of their atomic weight. Thus arranged, he showed that substances which came in certain classes had certain properties in common, as, for example, fluorine, chlorine, iodine, and bromine. But there were gaps in this scheme, and Mendelieff predicted that new elements would be discovered to fill the vacant spaces. The fulfilment of that prophecy was one of the greatest scientific achievements of recent years, and each new kind of atom had fallen into and fitted an empty place. In 1894 Lord Rayleigh and Sir W. Ramsay detected argon in the air. Next year Sir William discovered helium, which had been revealed in the sun by the spectroscope before it was found on earth. Two years later, in 1897, when the British Association met in Canada, Sir William Ramsay ventured on the prophecy that other elements like argon and helium would be discovered. He and a scientific colleague justified the forecast. They searched high and low, and finally by means of liquid air they isolated three new elements in the atmosphere—krypton, neon, and xenon—belonging to the same class as helium and argon, and like them inert bodies with no discoverable affinity for others. The professor showed what gases of these substances were like by sending through them an electric current. Their spectra were thrown on the screen, that of xenon, or "the stranger," showing in its entirety the remarkable number of 2,000 distinctive lines. These, it had been said, were inert elements. Their discovery had been followed by the revelation of a class of elements that were remarkably energetic. In 1896 Röntgen discovered the X-rays, and Prof. Ramsay showed a radiograph, the first he believed taken in London by the Röntgen rays. Simultaneously Becquerel, in Paris, discovered that uranium would discharge the electroscope. Madame Curie, following up the investigation, revealed the existence of polonium in pitchblende, and in the same mineral Monsieur and Madame Curie made the momentous discovery of radium—now universally known as the most energetic of all radioactive bodies. But not the only one; there seemed to be six in all—uranium (found by Becquerel), polonium and radium (Monsieur and Madame Curie), thorium (Schmidt, of Breslau), tinium, and an unnamed element (by Gresel). As to what became of radium ultimately, Sir Wm. gave it as his opinion that the infinitely small particles that it threw off eventually lost their radioactivity, and then gave the spectrum of helium. It seemed as if this intensely active element at last turned into helium—thus bearing out the theory of transmutation.

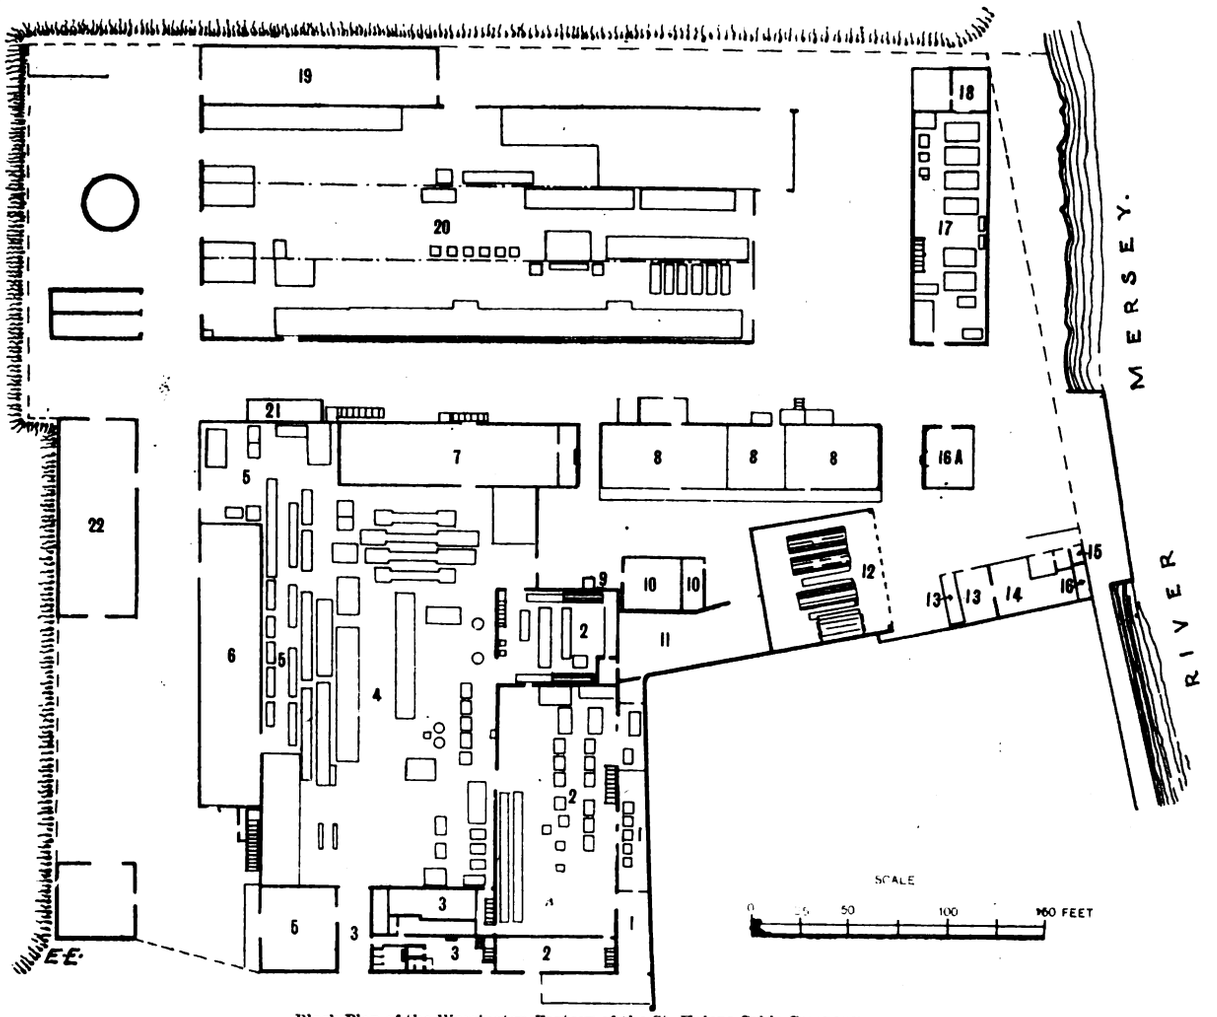
WORKS' VISITS.

I.—The St. Helens Cable Company, Limited, Warrington Factory.

It is not intended that the following article shall be an exhaustive description of the above factory. Passing reference only will be made to the departments engaged otherwise than in the manufacture of electric cables or the preparation of insulation for same. Regarded as a whole, the factory is a striking example of home progress and enterprise. The company originally established themselves at St. Helens, as the title implies, and their Warrington factory may thus be regarded as an overgrowth. Hitherto the Warrington factory has depended upon St. Helens for its wire supplies, but arrangements have now been made, we understand, to render it self-contained in this important respect by the addition of a wire-drawing plant capable of turning out 75 tons per week. The necessary accommodation for this plant is already provided. In the selection of a site for their new factory the company made a particularly happy choice, both the railway and water facilities offered being exceptional. During the past four years the factory has been quadrupled in extent, and the directors have secured 66 acres of the adjoining land with a view to further developments in the future. The company is now under new management, and the complete reorganisation has led to both economies in manufacture and improvement in details.



Block Plan of the Warrington Factory of the St. Helens Cable Company.

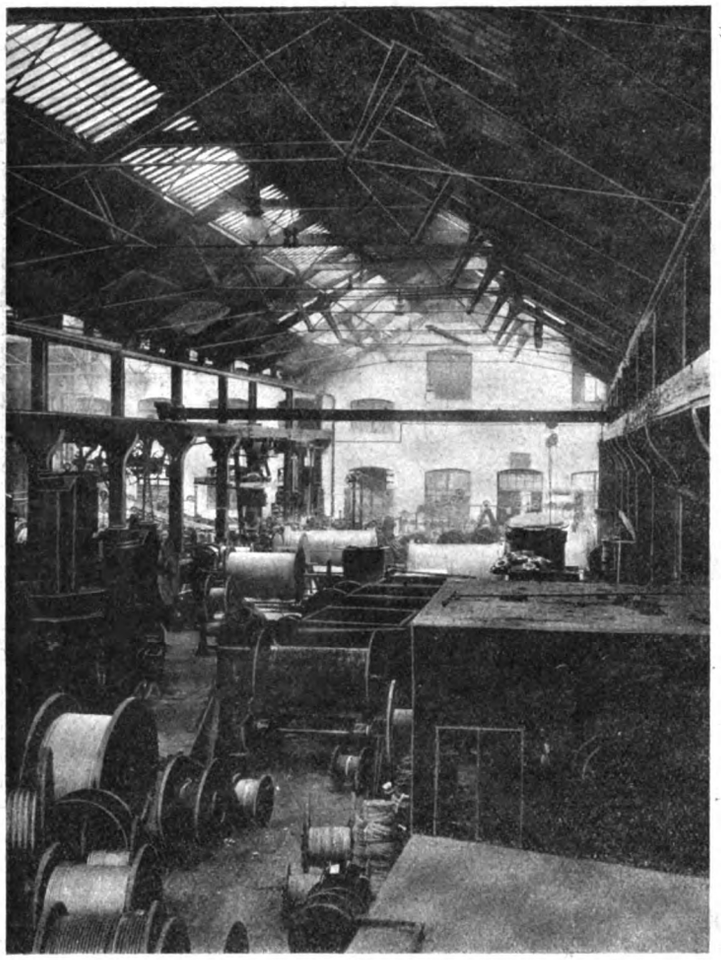
The general arrangement of the existing buildings is shown on the accompanying plan, the numbers on which indicate the different shops as follows: (1) raw rubber stores and rubber-washing room; (1A) rubber-buffing room; (2 and 2A) drugrooms and rubber manufacturing department; (3 and 3A) offices and cable-testing room; (4 and 5) electric cable manufacturing sheds; (5A) cotton-covering room for small wires; (6) copper and raw material stores for cable manufacture; (7) engineering department; (7A) joiners' and carpenters' (drum-makers); (8) compound shed; (8) iron and brass foundry; (11) power-house; (11A) finished rubber goods warehouse; (12) boilers; (12A) rubber-drying room; (13 and 14) cable-jointing shops; (15) pump-house; (16A) electric motor repair shop; (17) rubber-spreading shop; (17A) rubber-drying room; (18) laboratory; (19) dry-core cable-testing room; (20) dry-core cable-manufacturing shed; (22) waiting test-room. The lettered numbers refer to first-floor rooms.

Rubber Department.

Upon entering the works we were at once conducted to the rubber department—marked 1 and 2 on plan—which may be regarded as the nucleus of the whole establishment. The first room visited was the raw rubber stores, where a large stock of all the finer grades of rubber is stacked in bins. An average stock of over 50 tons is kept in these stores, representing in itself a large amount of capital. We next entered the boiling and washing section, the raw rubber being first boiled in large tanks containing a special solution, and then passed successively through a massive three-roll crushing mill, washing and sheeting mills, until thoroughly cleansed from all impurities. After this treatment the rubber is stored away in large drying chambers, kept at a constant temperature of 110deg. F., where it remains for some weeks until the sheets are matured. We then proceeded to the mixing section, where the various qualities of rubber are made up and consigned to the mixing mills. This is an important operation, and only the most skilled operatives are engaged in it; thereby ensuring the best results for the various purposes. Subsequent to the mixing process the batches of compound are rolled out, through one or other of the three large calenders available, to the required thickness. It should be mentioned that the machinery in this department is of the latest and most up-to-date kind. The calenders and mixing and washing mills are arranged on three main shafts. The first of these shafts is driven by a 200-h.p. engine, and carries six

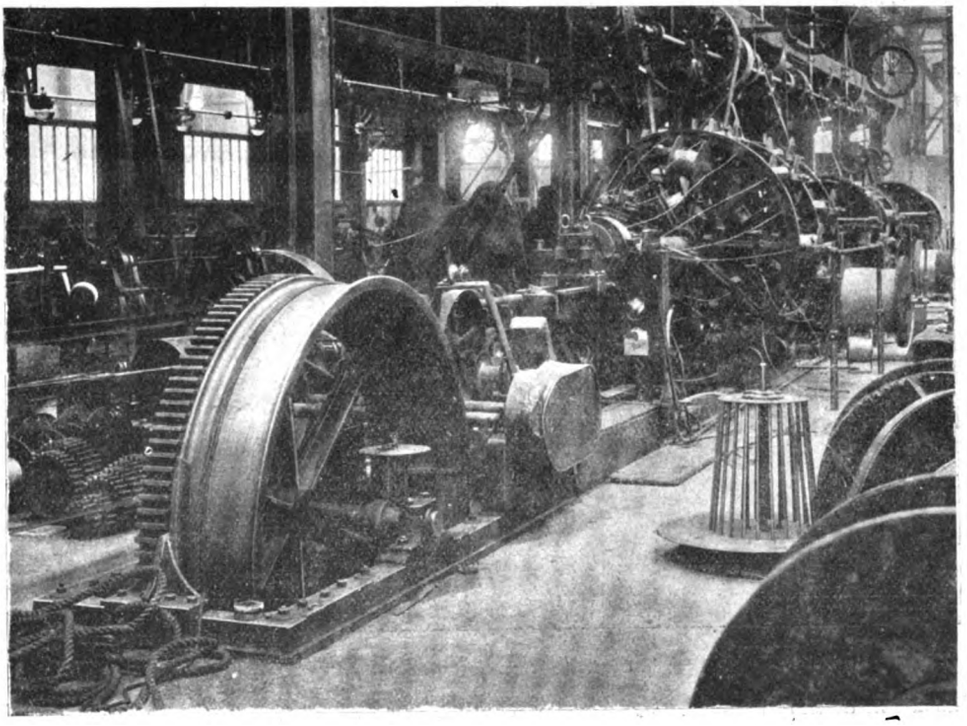
Digitized by Google

mixing mills and one three-bowl calender; the second shaft, driven by a 350-h.p. engine, carries three small



Bay in the Main Cable Shop.

washing mills, one large two-roll washing mill, one large three-roll washing mill, one mixing mill, and one three-bowl calender; while the third shaft, driven by a



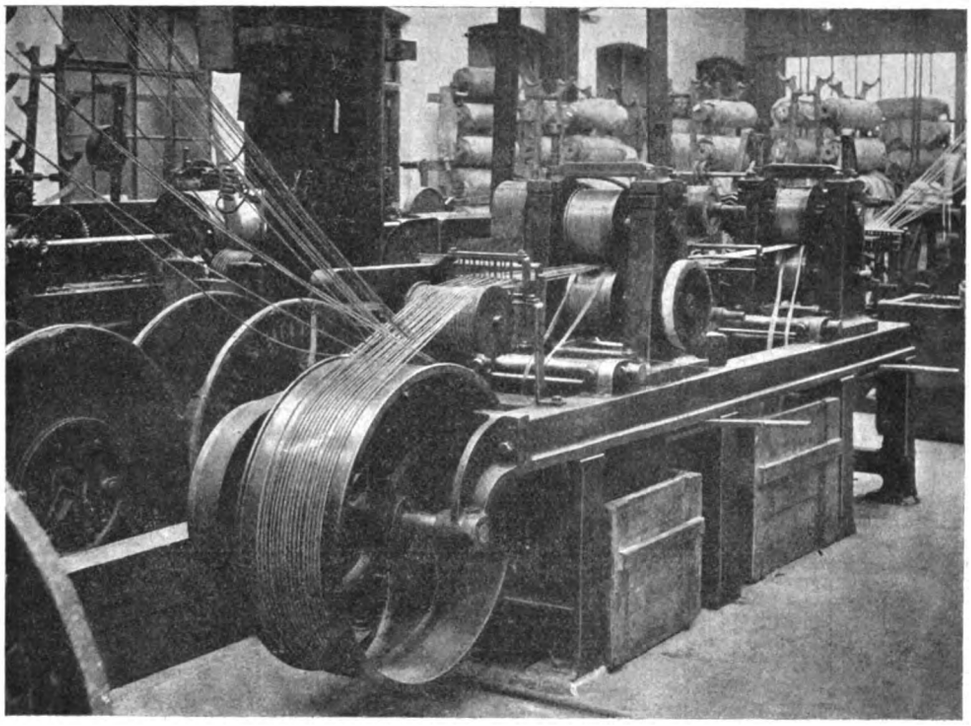
Stranding Machine in Main Cable Shop.

120-h.p. electric motor, carries three mixing mills and one three-bowl calender. Although primarily intended to provide the cable branch with its requirements in compound

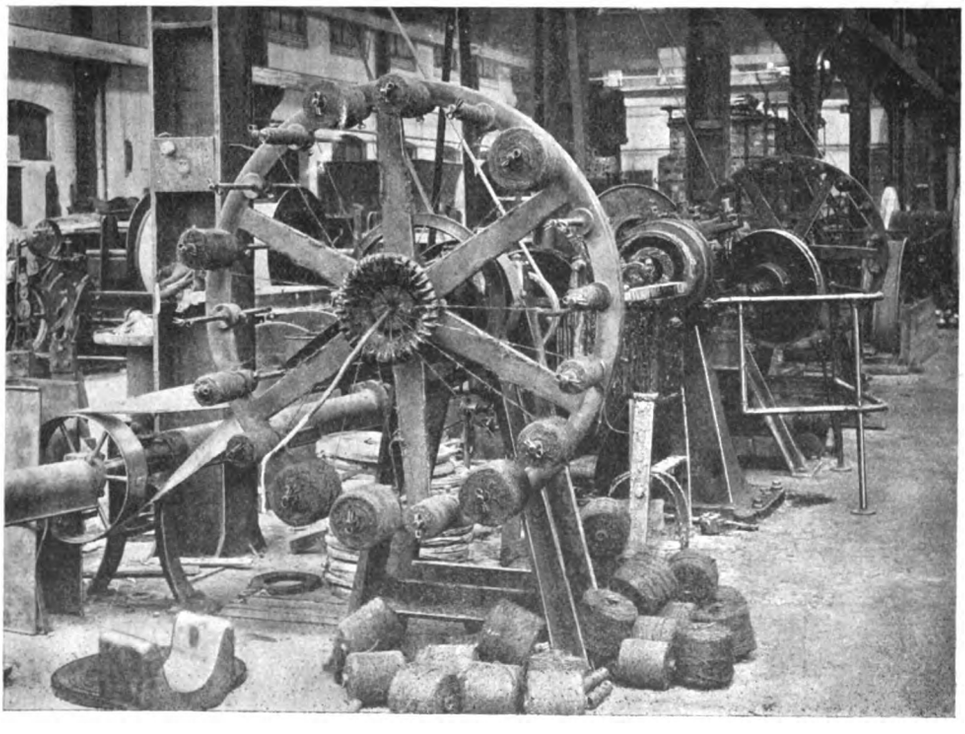
for the manufacture of vulcanised cables, this department has also established a reputation for mechanical and other rubber goods, of which the factory yields an enormous output. This fact has an important bearing upon the organisation of the factory, which is invariably busy in some when not in all of its branches. In the same building other machines were turning out cab tyres, tubing, etc. The manufacture of the firm's cab tyres alone keeps a large

Digitized by Google

number of hands employed, several tons of these tyres being dispatched from the works weekly. Having witnessed, for our own satisfaction, the operations which the production of this class of goods entails, we passed on to the press and curing shops. Here we were surrounded by vulcanising pans, hydraulic and belt-driven presses of all shapes and sizes, accumulator and powerful hydraulic pumps, etc. Thence we proceeded to the moulding room and witnessed the manufacture of a bewildering array of rubber goods of every conceivable description—balls, buffers, pedals, blocks, insulating materials, etc. The next move was to the mechanical rubber section. Here we saw large rolls of sheets and insertion, valves, washers, cylinders, rubber gloves, mats, etc., and more vulcanising pans, together with large drums for lapping sheets. Then we came to the lathe and buffing room, with its long line of lathes of various patterns and designs, sewing machines, leather-cutting and rolling machines, packing making rolls, etc. It may be explained here that some of the rooms mentioned in the foregoing, and others of which subsequent mention will be made, are situated on the first floors of the respective branch buildings to which they belong, and are consequently not shown on the accompanying plan. From the last-mentioned room we crossed the yard to a new building—marked 17 on plan. This is the rubber-spreading shop, and contains seven splendid steam-heated spreading machines, with their necessary accompaniment of dough mills, masticators, etc, all electrically driven. Here operatives were spreading sheets of pure rubber and all kinds of insulating tapes and cloths. Overhead is a large chamber for maturing the pure sheets; also a well equipped laboratory, entered through a fire-



Longitudinal Machine in Main Cable Shop.



Armouring Machine in Main Cable Shop.

Digitized by Google

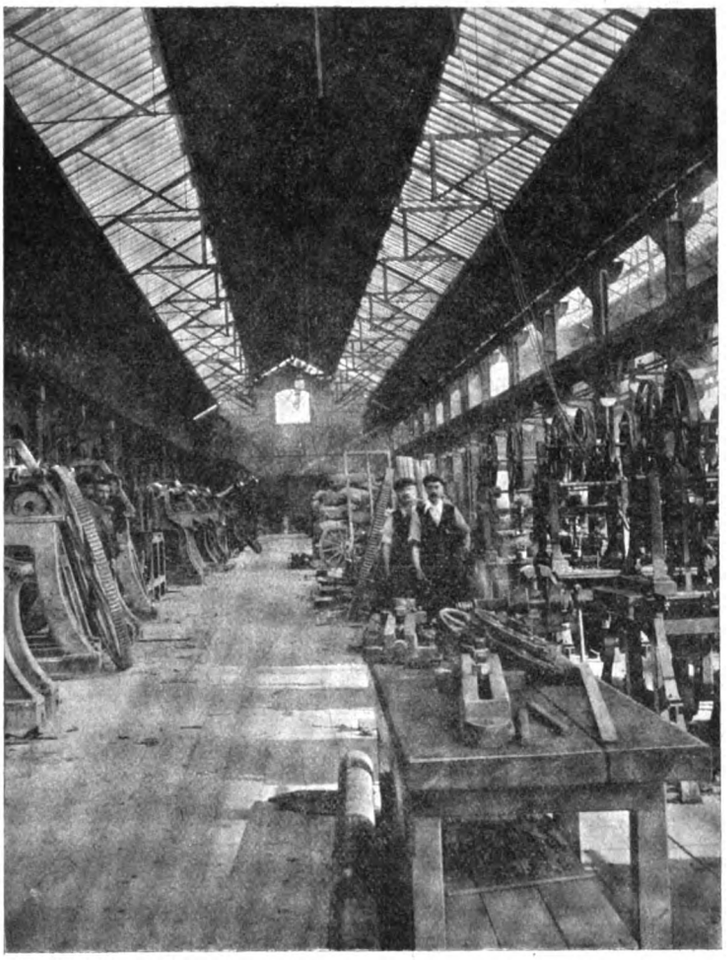
proof door. This laboratory is under the control of an expert chemist, and contains all the necessary apparatus for experimenting and testing the firm's various products and proving the quality of raw materials before these are passed into the factory. Among other apparatus we noticed delicate specific gravity balances, a powerful Zeiss microscope, experimental mixing mills, and calenders, etc. The material stores next claimed brief attention. These are extensive, and contained a large stock of fabrics—such as linen, cotton, flax, hemp, jute, etc.—for the various purposes of the factory.

Cable Department.

Proceeding, we arrived ultimately at the cable department itself. Cables are the firm's principal manufacture, and the factory has been designed with a view to the efficient and speedy handling of all sizes, ranging from the smallest instrument wire to the largest power or telephone cable. Roughly speaking, this department consists of three shops, with stores and testing-room conveniently arranged, so that delays and labour handling are reduced to a minimum. These shops may be designated respectively the main cable shop, the dry-core cable and paper insulating shop, and the cotton and silk covering shop. The two first-mentioned occupy the positions marked 4-5 and 20 on the accompanying plan, and measure 280ft. by 140ft. and 300ft. by 120ft. respectively, while the third—a first-floor shop, and consequently not shown on the plan—measures 280ft. by 40ft. As regards equipment, these shops are laid out with a complete plant of modern machinery.

The main cable shop is traversed throughout its entire length by four electric gantries, and contains plant for the manufacture of cables with single, concentric, or triple-concentric conductors, either paper, rubber, or dialite insulated, and for lead covering and armouring the same as follows: one triple-concentric Bulmer stranding machine to lay up 37 single wires in one operation; one 18-bobbin high-speed strander; one 6-bobbin high-speed strander with four heads; four longitudinal compound rubbering machines to deal with 8, 12, 18, and 24 wires respectively; seven pure rubber covering machines; one 4-headed and two 5-headed dialite insulating machines; one 3-headed paper and taping machine; one 4-headed taping machine; one 4-beaded vertical taping machine; four 24-spindle braiding machines; eight 18-spindle braiding machines; one steel-taping machine, fitted with two jute serving heads and two compounding tanks; three rubber-cutting lathes; one lead press with 20in. to 8in. diameter ram; one lead press with 26in. to 6in. diameter ram; one lead press with 26in. to 8in. diameter ram.

The lead presses enumerated in the above list are worked by electric motor-driven pumps, supplying water at a normal pressure of $1\frac{3}{4}$ tons per square inch, and each is capable of covering any cable up to 3in. diameter. Serving this shop there are also three vulcanising pans, each of which will take a 9ft. by 4ft. 6in. drum of cable; five steam-heated ozokerite tanks for impregnating purposes, each of which will take a 8ft. by 5ft. drum of cable; and four long ozokerite tanks for compounding small cables.



Bay in Dry Core Shop.

The dry-core cable and paper-insulating shop is laid out more especially for the manufacture of telephone cables and paper-insulated cables generally. It contains at present the following plant: one large telephone cable laying-up machine; 40 vertical papering heads for telephone wires; 12 telephone wire-pairing machines; four 24-spindle braiding machines for braiding telephone cables; 12 Keighley stranding and papering machines; two four-headed papering and tapering machines; one six-headed vertical high-speed strander; one four-headed vertical high-speed strander; one 12-bobbin closing juteserving and compounding machine; three vacuum drying ovens for telephone cables; one continuous hydraulic lead-covering press with 26in. to 8in. diameter rams, supplied by a set of electromotor-driven pumps.

As might be surmised on referring to the dimensions given elsewhere, this shop is not yet fully equipped. The wire-drawing plant, of which previous mention has been made, is destined to ultimately occupy one bay, while new

Digitized by Google

machinery is to be added, we understand, to increase the works output of rubber and dialite insulated cables. In close proximity there has just been erected a gas-producer plant, with the necessary provision for storage, designed to supply gas for heating purposes. This plant may be said to represent the latest addition to the works.

The equipment of the *cotton and silk covering shop* is as under: 32 pure rubber coating machines; 96 16-spindle, 24 24-spindle, six 20-spindle, four 32-spindle, one 60-spindle, and one 28-spindle braiding machines; 32 silk-covering machines; 80 cotton-covering machines; one 19-bobbin, one 7-bobbin, and one 4-bobbin stranding machine; three flexible stranders. As its name implies, this shop is devoted entirely to the manufacture of cotton and silk covered wire for armature winding, bells, telephones, etc. It is capable of supplying every description of cotton-covered and braided wire, strip, and cable, and has an output of many tons per week.

It is beyond the scope of this article to describe the various machines comprising the equipment of these works, but to one at least must be accorded more than passing mention. We refer to the telephone cable laying-up machine installed in the dry-core cable and paper-insulating shop. This machine consists of three sections, each capable of being driven separately, or the whole driven together by a 50-h.p. electric motor. It is designed to lay up a 306-pair telephone cable, or, if necessary, even larger cables, at one operation, and occupies the whole of one bay, 300ft. by 40ft.

No description of this department would be complete without reference to the testing equipment provided. The galvanometers are all of the highly sensitive D'Arsonval

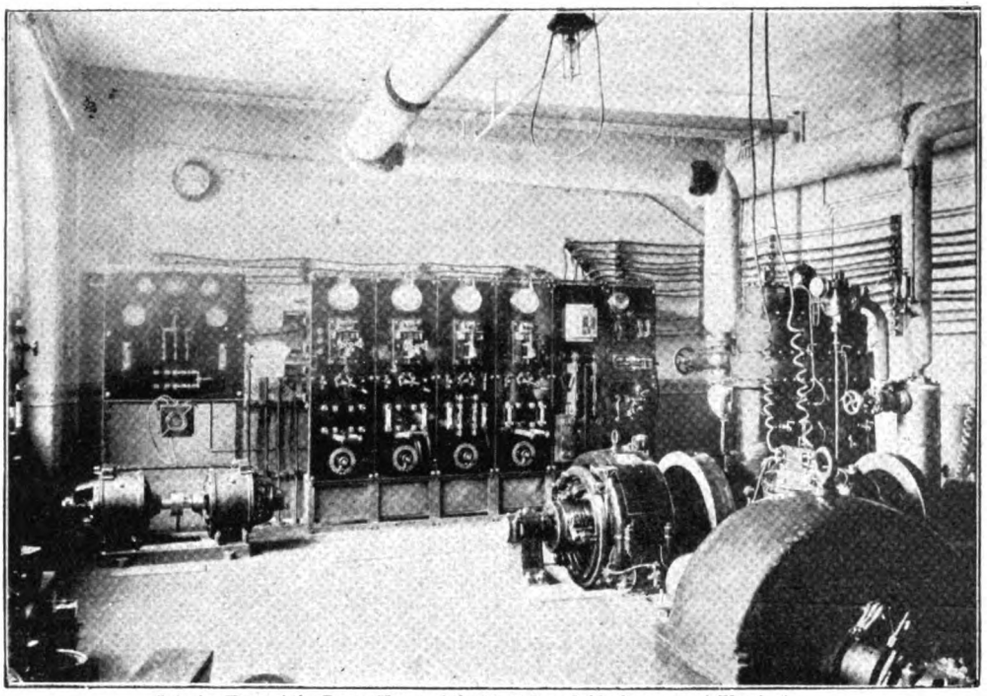
type, mounted on substantial brick pillars, the test keys being mostly of the well-known Rymer-Jones pattern. The pressure to each set is 600 volts, which may be sub-divided at will by means of elaborate battery commutators. All the tables on which the sets are mounted are of special design with a view to economising space. The high-

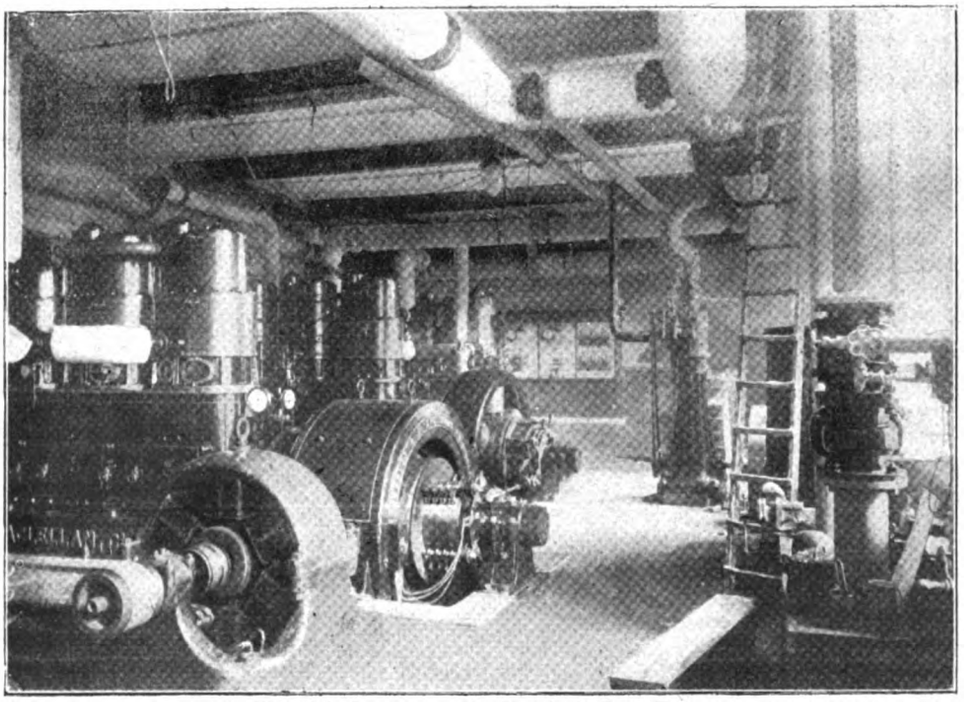


Interior View of the Power House of the St. Helens Cable Company at Warrington.

potential testing apparatus consists of a large alternator and step-up transformers, an electrostatic voltmeter for reading up to 5,000 volts, and a large Kelvin balance for still higher pressures up to 100,000 volts. There is no lack of tank room, eight large tanks being in daily use for the immersion of cables and wires. All results of tests are permanently recorded, and can at any time be quickly turned up for reference.

appreciated by many of the leading collieries in the United Kingdom. Dialite cables have also been largely used in connection with a number of public electric lighting and traction schemes. It may be explained here that dialite is bitumen vulcanised by a special process. We were shown through the rooms in which the crude materials are boiled down, also the subsequent manufacture of the product into sheets of insulation bearing a very strong resemblance in texture and mechanical properties to rubber. Among others, Mr. Wordingham and Mr. Adams, of Glasgow, have reported upon dialite insulation for cables, the results of the tests given being eminently satisfactory in every respect.

At the time of our visit to the works there were on the



View of the Larger Generating Plant in the Power House.

Of the company's various manufactures, dialite insulated cable takes the first place in importance, being a speciality which has come rapidly into prominence of late. The most important claim made in favour of this cable is that it is absolutely non-hygroscopic, thereby obviating the necessity for lead sheathing. It is, therefore, peculiarly suitable for colliery work, a fact which has been deservedly

machines, in various stages of progress, many large cables destined for ultimate use in this and other parts of the globe. Our particular attention was called to a concentric cable of one square inch sectional area, paper insulated and lead covered, made to the order of one of the Colonial Governments; also to a three-core dialite insulated cable intended for colliery work. The feature of the latter cable

Digitized by Google

is that the interstices between the insulated cores are filled with dialite insulation instead of the usual jute or hemp worming. The result is that, after vulcanisation, the conductors are enveloped by a solid homogeneous mass of dialite. Sections are reproduced herewith of one of the cables which were going through the different shops at the time of our visit. These will convey an idea of the variety of cables made to recent order.

Auxiliary Departments.

Brief reference may be made to the engineering department of the works, marked 7 on the accompanying plan. This is laid out for the repair of any class of machinery in the factory, and the manufacture of light insulating machines generally. The smithy attached contains two hearths and a pneumatic hammer. A joiners' and carpenters' shop is provided for the manufacture of cable drums and executing general repairs. There is also an iron and brass foundry, 80ft. by 30ft., marked 8 on plan. Joint-boxes are made here, also fittings and castings used in making the machinery erected in the engineering shop, etc. Attached is a 50cwt. cupola, blown by a Root's blower, direct coupled to an electric motor; also a 3cwt. open-hearth brass furnace, six brass crucible furnaces, and a complete sand-blast plant. It now remains to deal with the power and lighting plant, which is no small item in an establishment the size of that under notice. On our way to the power-house we gave the dispatch department brief attention. This department is interesting, in that it represents the final stage in progression to which all cables, etc., manufactured in the works come, and it is here that we get a vivid idea of the amount of work turned out by the factory per day. In this connection mention may be made of the fact that the packing-room has had to be enlarged recently in order to meet growing requirements. Although a railway station practically adjoins the factory, the need has been felt of a direct railway connection, as the method of dispatch by cart to the station is, especially for large and heavy consignments, at times inconvenient. Hitherto the factory has lacked such connection, but this defect will soon be remedied, as the London and North-Western Railway Company are, concurrently with the widening of their main line to the North, putting in a private siding. When this work is accomplished, the St. Helens Cable Company will be in a position to reap the full advantage of a site inherently good. The bulk of the raw materials consumed by the factory, including coal from the neighbouring collieries, is water borne, and enters the works from the quayside.

Power and Lighting Plant.

It is on this side that the power-house is established. The steam-producing plant consists at present of three Lancashire and one Babcock-Wilcox boilers, each capable of evaporating on an average day load 8,750lb. of water per hour. Superheaters are fixed in the down-take at the back of the boilers, and two Green's economisers are in use, the scrapers being driven by electric motors. Condensing plant of the most approved type is also installed.

The engine-room equipment includes one British Thomson-Houston 230-kw. dynamo, one Bruce-Peebles 205-kw. dynamo, and one Lancashire Dynamo Company's 86-kw. dynamo, each of these dynamos being coupled direct to an Alley and Maclellan's high-speed compound single-acting engine. In addition to this plant there are two engines of the same type and make as the above, aggregating 500 h.p., driving the shafting for the rubber mills direct.

As regards the design of the electric installation a noteworthy feature is the entire separation of the power and lighting circuits, separate switchboards being used for each. The lighting current is distributed from a three-wire system at 230 volts pressure, the generators being wound for 460 volts corresponding to the pressure in the power mains. A General Electric Company's balancer is used for balancing the three-wire system. Throughout the factory there are about 80 motors in use, ranging in power from 3 h.p. to 120 h.p. These are employed for driving line shafting or cranes and machinery direct. The supply is conveyed to the different buildings by underground mains in earthenware ducts and by overhead-line conductors.

Our thanks are due to the company's secretary (Mr. F. Kenyon) for assistance rendered in the preparation of the above article, and to their energetic works manager (Mr. H. R. Garrard) for his courtesy in conducting us over the factory.

INDEPENDENT TELEPHONY IN GREAT BRITAIN.

BY GARDNER AND HOLME.

(Continued from page 803.)

(7) Junction and Trunk Lines.

As already mentioned in a previous article, in order to connect up for communication the various outside villages with the main exchange, junction wires become necessary. These junction lines generally diverge from the main exchange, as will be seen on reference to Fig. 1. It will also be seen that while two exchanges are entirely isolated, the others (two) are in the same direction, thus reducing the cost of construction and maintenance.

In the erection of the junctions for Portsmouth, which were excessively long, only two main routes were necessary to connect up six outside exchanges. Junction lines generally start at the termination of the main underground cables, and are then carried overhead on creosoted wood poles along the main turnpike roads or highways where wayleaves are accessible, the wayleaves being obtained from the county and district councils; but where engineering difficulties are experienced in the roads through obstacles and trees, application is made to the private owners of the several properties over which the line of the poles is proposed to be erected. Difficulties are seldom experienced in the obtaining of these consents if the landowners are approached in the first instance and agreement entered into. A form of application is shown in Fig. 35.

In taking up this work, the engineer-in-charge should begin by making a preliminary survey, and being provided with a complete set of Ordnance maps (6in. to the mile), he should walk or drive over the different roads along which it is proposed to erect these lines. As soon as the route to be followed is decided upon, application should be made to the local authorities at once in order to save delay. From the information collected the private wayleaves are generally ascertained, but in order to save many difficulties it is best to obtain the services of a good local man in the obtaining of these, as he will be thoroughly acquainted with the district. Following the preliminary survey, a detailed plan should be made up after the following manner: (1) the position and number of the poles as near as possible; (2) particulars of crossings; (3) methods of staying the poles; (4) private consents required; (5) the means obtainable for laying-out the poles by traction or cartage, traction being by far the best and cheapest method. The detailed plan or working survey is the key to the success of the whole operation, and if prepared thoroughly will save time, expense, and many alterations after the work has been completed, and will show the foresight and experience of the engineer by the appearance of the line.

The surveying engineer should be accompanied by the foreman who is to take charge of the work and a few labourers to mark off the proposed position of the poles and measure up the lengths of the spaces between each pole. These positions might be marked by driving in hardwood pegs into the ground painted on top with white paint. This method cannot always be relied upon, and a better one is to draw up a survey book entering all information while on the spot, such as landmarks on the road, for future guidance. Fig. 36 shows a useful form of book. A will give the number of each pole consecutively from terminal or distributing pole at cable end to the exchange pole at the village proposed to be connected; B the position of the pole in the roadway, hedge line, or bank, this being a guide to the hole diggers in case of the marks being lost; C the length of the pole in feet, extra or special poles being marked accordingly; D the distance in yards between the poles; E the number and position of the stays. F, the remarks column should be as large as possible in order to note down all special information as to consents, single and double line stays, and all such points that will be of service to the

foreman when carrying out the work. The survey should be so complete that anyone would be able to follow without difficulty the proposed route. In selecting the side of a road, the line should be kept as straight as possible, and the side chosen clear of obstacles and trees, preventing as much as possible the overhanging of the centre of the road in long spans with the wires. An

Survey Book.

Fig. 36.

necessary to the fitting of struts. Consents should be obtained on the printed forms, signed and dated, verbal consents not being legal and always leading to disputes and trouble. The license granted to the authority by the Postmaster-General generally confers with it wayleave powers, but it is important that accurate information be obtained as to the owners and occupiers whose consent is necessary to the erection of a line. All information of the local authorities controlling the highway should also be recorded, and the Telegraph Acts of 1863 to 1892 understood before taking any risks. The consents and survey being made up, a schedule should be prepared from the details and plan, showing the stores and materials necessary to carry out the junction work, and also an estimate of the cost.

Hole Digging.—This part of the work might be let out to contract at a price per hole, under the supervision of the foreman, who could mark off the holes, giving instructions as to position of digging and depth, and so arrange the works as to keep the hole diggers well in advance of the erecting gang. The holes generally are dug in line with the wires so as to get the solid earth on both sides of the pole. Poles should be buried to the usual depths, and the

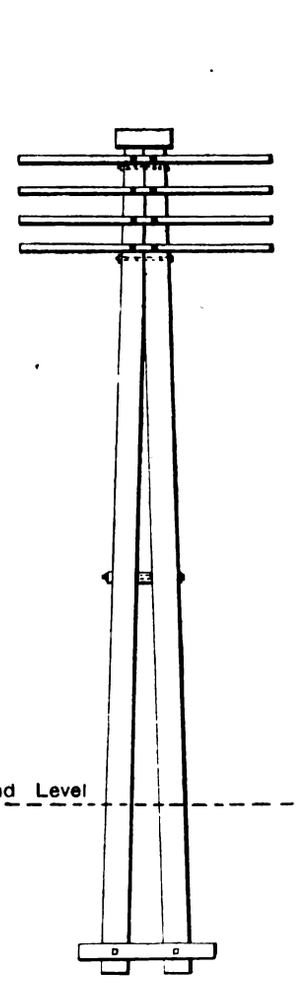

Fig. 37.—A Pole.

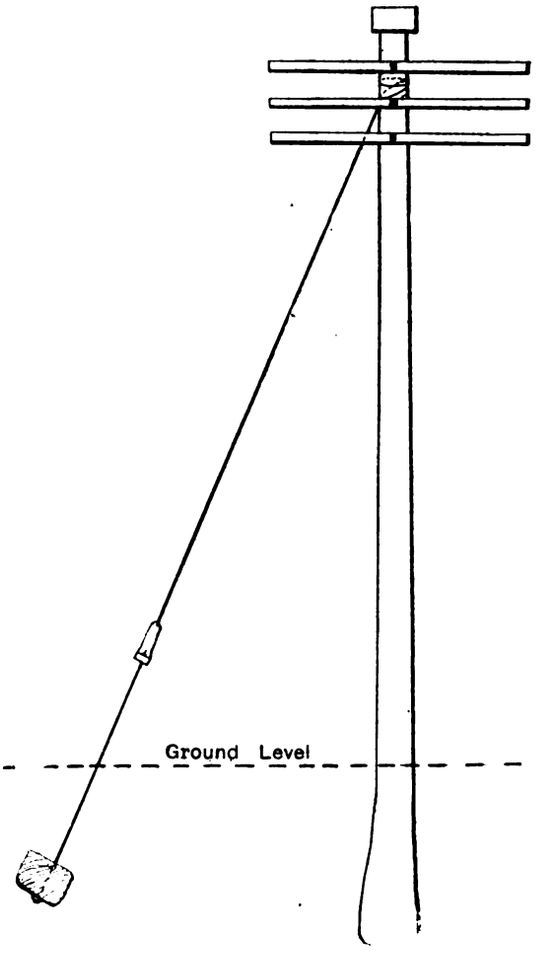

Fig. 38.—Pole, showing stay and method of fixing.

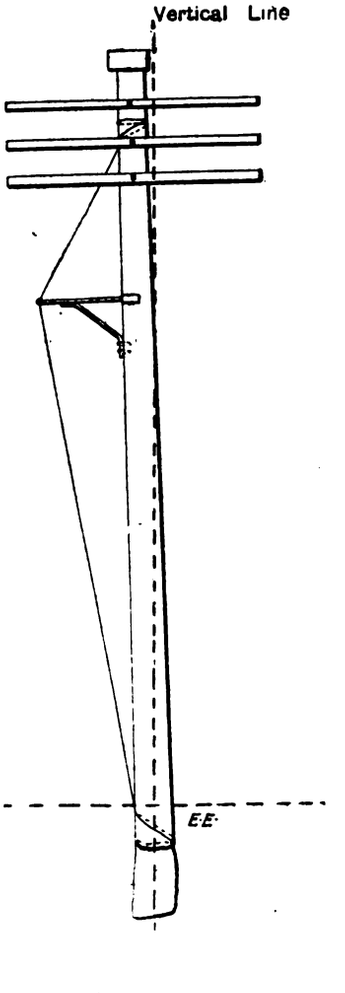

Fig. 40.—Pole with Outrigger.

irregular line of poles is unsightly, and always leads to comment. Poles should be kept regular both in height and distance apart, well stayed, strutting being avoided. It is often better to cross the road and stay back the poles to avoid strutting, as workmen do not give the attention

Digitized by Google

foreman given a written copy in order that he can check each pole, the poles being marked and dated 10ft. from the butt. For creosoted poles in ordinary soil the following depths for planting will be found adequate for junction lines:

DEPTHS FOR PLANTING WOOD POLES.

Length of pole.	Depth in ground.	Length of pole.	Depth in ground.	Length of pole.	Depth in ground.
26ft. ...	4ft. 0in.	... 36ft. ...	5ft. 0in.	... 50ft. ...	6ft. 0in.
28ft. ...	4ft. 3in.	... 40ft. ...	5ft. 3in.	... 55ft. ...	6ft. 6in.
30ft. ...	4ft. 6in.	... 42ft. ...	5ft. 6in.	... 60ft. ...	7ft. 0in.
32ft. ...	4ft. 9in.	... 46ft. ...	5ft. 9in.	... 65ft. ...	7ft 3in.
34ft. ...	4ft. 9in.	... 48ft. ...	5ft. 9in.	... 70ft. ...	7ft. 6in.

Erecting.—For junction lines creosoted poles of from 26ft. to 45ft. will be found ample in height, the local circumstances, clearance, and number of wires governing each individual case. For this class and size of pole ladders will be found the best for erecting, the ladders being made specially for the work. The poles should be set well against the pull of the wires; 12in. on the head of the pole from the vertical line will be found none too much on sharp angles, and in special cases poles might be blocked with timber 4ft. by 6in. by 6in., to keep them from coming over with the pull, about 12in. or 18in. below the ground line and also at the base. This method should be adopted in soft marshy soil and bog land. The soil around the poles should be thoroughly rammed and punned during the filling in, and all surplus soil removed. Holes should never be left open unguarded or during the night, and the work should be organised so that all poles are erected for the number of holes dug out during each day. On very sharp angles and where staying powers are impracticable A poles are best, and form a very rigid structure, as shown in Fig. 37.

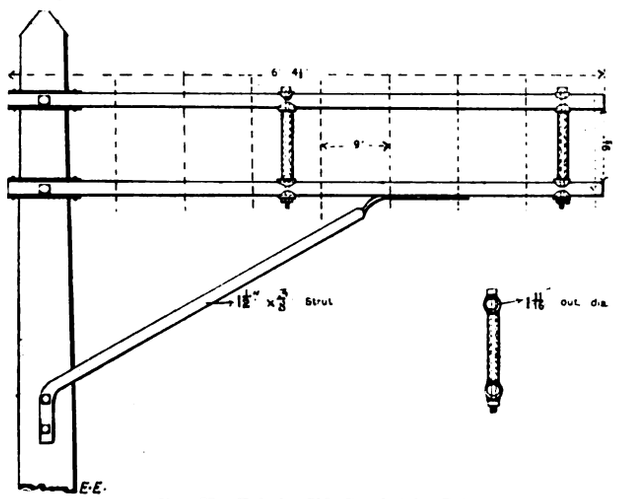

FIG. 39.—Tubular Side Bracket for Pole.

Mounting.—The mounting of the poles is generally done by a gang of men in advance of the hole diggers and erectors, as it requires care and time to fit and mount poles correctly, and none but good men accustomed to the work should be employed. Immediately following the laying-out the mounting gang ought to follow up and fit the poles with roof, earth wire, and arm. The mounting gang should be given instructions as to the fitting—that is, in the fitting of the galvanised iron roofs or finials, the side of the pole to earth wire for the protection against lightning, the number of slots to cut out for the arms, and the number of holes to bore out for bolting the arms to the pole. It has always been found good practice to cut and bore out more slots than are necessary for present use, while the poles are on the ground. Fig. 38 shows the necessary fittings with stay fixed ready for wiring. Fig. 39 shows the method of wiring a pole to clear trees where it is impossible to get through with open wires in the ordinary way. Where this method is adopted the poles should be set well back and rigidly stayed against the weight of the arm and wires.

Staying.—As already mentioned, this is done to prevent a pole being pulled over with the angle of the wires. Special stranded galvanised wire is used for this purpose either of iron or steel, $\frac{5}{8}$ or $\frac{7}{8}$ wires, being twisted together. Iron is better and more suitable for the work. In the fixing of stays on a pole they should always be clear of the arms, so that the arms are free for removal at any time. The following table gives the relative properties of galvanised iron and steel wires for staying purposes:

S.W.G.	Breaking strain.
No. 8	1,600lb.
,, $\frac{5}{8}$ strand	5,800lb.
,, $\frac{7}{14}$,, ...	5,820lb.

Poles should be stayed at every angle and line stayed every quarter of a mile, the most efficient position for fixing being the middle point between the upper and lower arms. The lower end of the stay should be attached to a stay tightening rod, these rods generally running 6ft. to 8ft. in length, and from $\frac{5}{8}$in. to 1in. in diameter. They ought to be buried in the ground 3ft. 6in. to 6ft., a large block of timber being used and fitted to the stay rod, acting as an anchor to the stay, the hole being undercut so as to get the block of timber well under the solid earth. The stay should be given as large an angle as possible, the base being a half to two-thirds the height of the resultant point above ground. Where this distance of base is not obtainable a stay bracket might be used and fitted, as shown in Fig. 40. Care should be exercised in the fitting of all stays to see that they will not come in contact with the wires, and at the base or ground line they ought to be protected by a blind post well painted.

(To be continued.)

A NEW COMPOUNDED THREE-PHASE GENERATOR.*

(Concluded from page 832.)

In the synchronous machine the pole winding is single phase, phase 2 being omitted. The current supplied to the

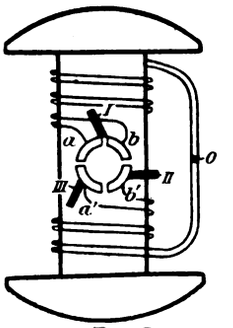

FIG. 5.

commutator is the whole main current, and the connections of the pole winding to the commutator must be such that, on the one hand, the separate brush circuits are never interrupted and, on the other hand, the current in the pole

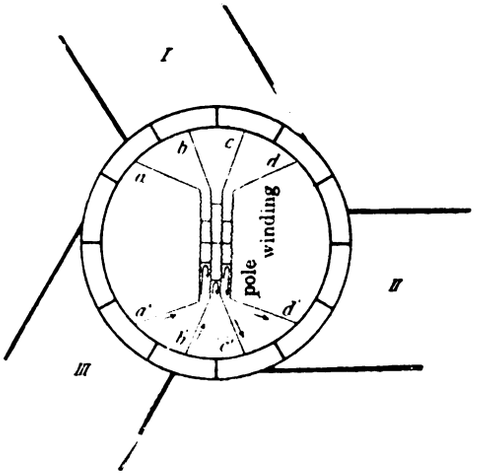

FIG. 7.

winding rises and falls proportionally to the wattless component of the main current. This is attained in the following manner: the pole winding consists, not of a single

* Translation of an article by E. Kolben in *Elektrotechnische Zeitschrift* for Oct. 8, 1903.

Digitized by Google

wire, but of two or more wires wound in parallel throughout their whole length, and these are connected to a commutator having a number of segments per pole corresponding to the number of parallel windings, interspersed, however, with

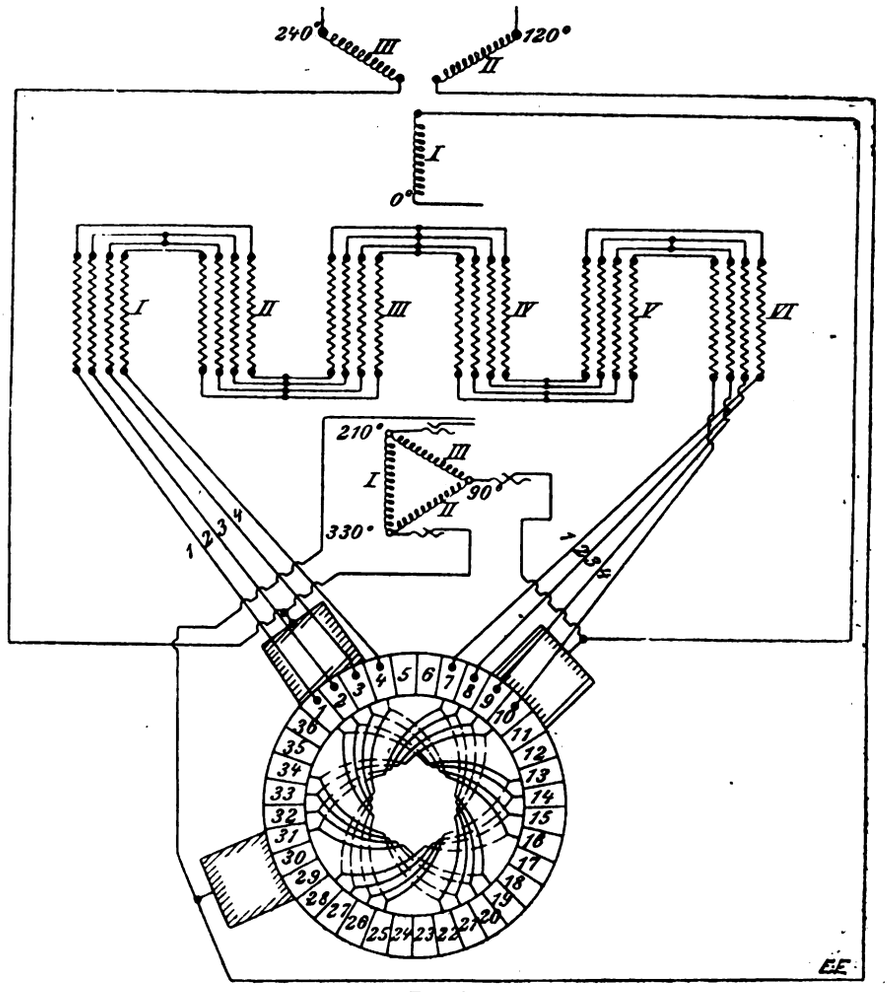

FIG. 6.

dummy contacts not connected to the windings at all. The simplest case is that shown in Fig. 5. The pole winding here consists of two parallel wires which are connected to the commutator, and also connected together in the middle at the point 0. The brushes are so set that the wattless currents

brush I, through the two wires, *a* and *b*, to the two ends, *a'* *b'*, and back through brushes II. and III. A power current may at the same time flow through the commutator, but would not produce any magnetising effect on the pole,

for it would flow from brush III. through *a'* to 0, and *b'*, and back through brush II.—*i.e*, it would flow in both the wires, *a'* 0 and *b'* 0, in opposite directions, and so produce no effect

Sparking is prevented at this commutator by the fact

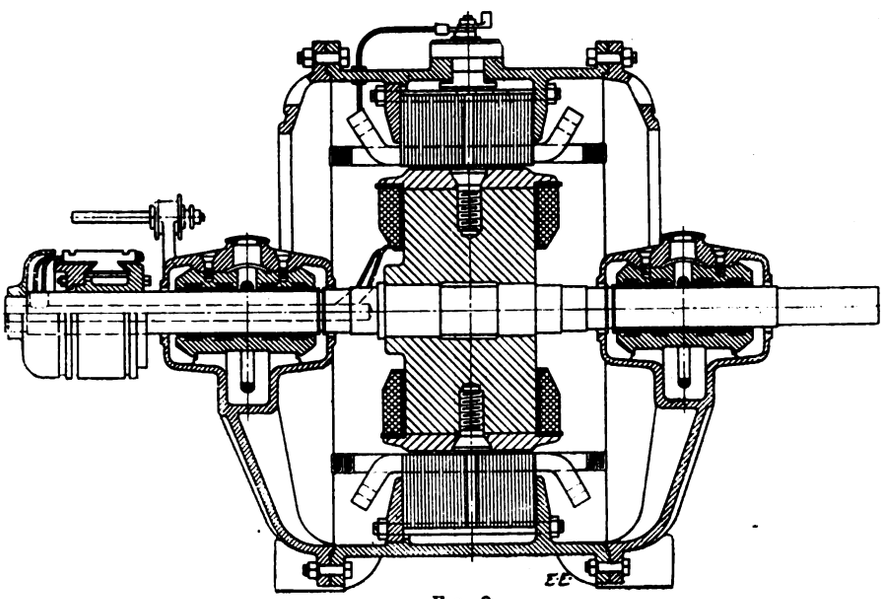

FIG. 8.

coincide with the direction of the magnetic axis, the power currents being at right angles to it. A wattless current will, therefore, always flow in one or the other winding, or in both in parallel in the same direction. In the position shown, for instance, a wattless current would flow from

that, the two wires being wound in parallel, whenever one is momentarily cut out of circuit the other remains in circuit and cancels the self-inductive effect of the disconnected wire. In actual practice the winding consists of more than two wires in parallel. Fig. 6, for instance,

shows the connections for a six-pole generator having four wires in parallel in each of the six magnet coils. The larger number of wires have the advantage that higher

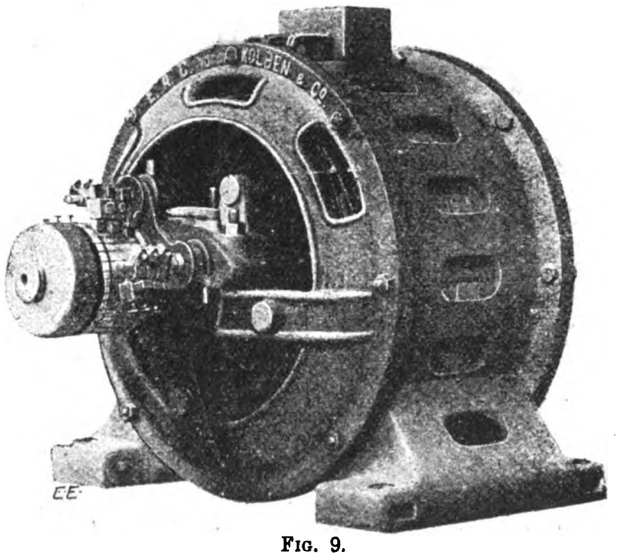

FIG. 9.

brush voltages and lower currents can be employed without sparking. Absolutely sparkless running is attained by an interesting arrangement also shown in Fig. 6. The

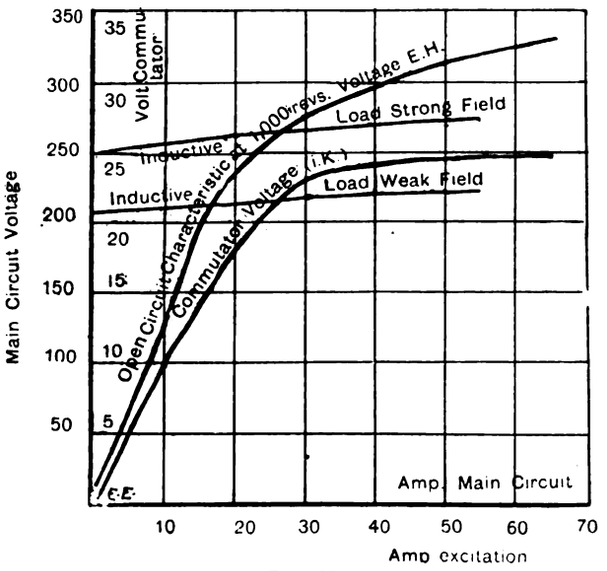

FIG. 11.

separate wires are interconnected at symmetrically arranged points starting from the centre point. In this way the voltage differences between neighbouring segments form a smaller fraction of the total brush voltage the greater the number of wires in parallel, so that higher brush voltages can be employed the greater the number of parallel wires. The arrangement has the further advantage that only a

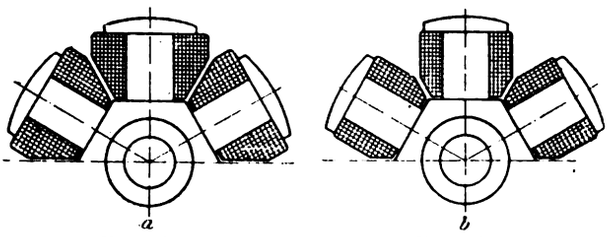

FIG. 10A. FIG. 10B.

comparatively small proportion of the power currents flow through the magnet winding, thus reducing the losses. In Fig. 7 the path of the power current is show diagrammatically by means of the arrows.

Figs. 8 and 9 show a section and general view of an ordinary three-phase machine fitted with the compounding commutator and radial poles. In consequence of the

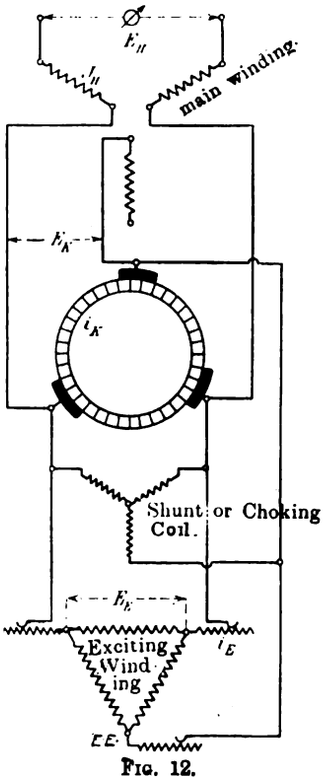

FIG. 12.

permissible reduction in air-gap, the weight of copper on the poles was reduced from 70 kg. to 50 kg. This reduction can be seen by a comparison of Figs. 10A and 10B. At the same time, in spite of the reduction in copper, the copper

Digitized by Google

loss in the poles with cos $\phi = \cdot 8$ fell from 4 per cent. in the ordinary machine to 2 per cent. in the compounded machine In the first experiments carbon brushes were employed to prevent sparking, but in order to reduce the brush losses these were replaced later by sheet-metal brushes without any sign of sparking. It was found best to employ several narrow brushes per brush spindle, so that by setting one behind the other the required number of segments could be covered.

The test results for a 20-kw. six-pole, 50 ⁓, 250-volt machine are given in Tables I. and II. It was an ordinary standard three-phase generator with its exciter replaced by a commutator, and its six magnet coils altered to suit the arrangement shown in Fig. 6. The open circuit and load characteristics are shown in Fig. 11. The regulation of the exciting circuit is carried out as shown in Fig. 12. A three-step resistance is employed for the voltage excitation, whilst for the adjustment of the main current excitation a shunt was employed in the one case (Table I.), and a three-phase adjustable choking coil in the other case (Table II.). The decided over-compounding which is seen to occur at one particular inductive load in Table II. is due to the magnetic saturation of the choking coil employed. The tests show that the machine also compounds with a weak field—*i.e.*, at about 200 volts—and shows an over-pounding of as much as 10 per cent. on inductive load.

As the compounding method described is applicable, with little alteration, to standard three-phase machines, the many advantages of compounded over separately excited machines are likely to lead to the rapid introduction of the method. Many such compounded generators, including some of 1,500 kw., are at present under construction in Messrs. Kolben's workshops.

DEPRECIATION ON ELECTRICITY UNDERTAKINGS.

The *Bolton Daily Chronicle* of Nov. 26 has the following:

Councillor Dr. J. E. Panton, chairman of the Bolton Corporation Electricity Committee, writes a lengthy letter to the current number of the *Journal of Gas Lighting* with reference to Bolton's position in the matter of depreciating its electrical undertakings. Bolton is compared with Scotch concerns, and Councillor Dr. Panton emphasises the fact that whilst Glasgow's sinking fund is only 1 per cent., that of Bolton is 3½ times that percentage. He goes on to say: It is usual for the Local Government Board to allow the English municipalities (outside London) for their electricity works at the most only a life of 25 years. Now the bulk of the Glasgow electricity debt is repaid either one-fortieth or one-fiftieth annually, while Bolton has only been allowed 23 or 25 years, and a more recent and larger sanction reduces this period still further—to only 22 years. This difference cuts into the very marrow of the question of depreciation. Evidently the Scotch Office is guided by experts of very different views from those of the Local Government Board, and I quite agree with you it is very desirable a commission should be appointed to consider the whole question. Our Electricity Committee is working on very nearly identical lines with those of Glasgow and Aberdeen as regards the year's result, as the following table will show:

Town.	Electricity capital.	Depreciation and sinking fund.	Percentage on outlay.
Glasgow	£1,041,746	£41,130	3·948
Aberdeen	194,079	8,537	4·398
Bolton	207,481	9,222	4·444

So that Bolton pays a higher percentage for depreciation and sinking fund together on its electricity capital account yearly than either Glasgow or Aberdeen. The errors published to the contrary are occasioned by the working out of the totals by the cost per unit sold. It seems that the electrical engineers in Glasgow and Aberdeen have had a freer hand than in Bolton. At all events, we in Bolton have not over-weighted the capital account of our undertaking for the units produced. When comparison is made per unit sold, the figures of depreciation and sinking fund come out: Glasgow, 0·859d. per unit; Aberdeen, 0·795d. per unit. Bolton only seems to put away 0·582d. per unit, while, as I have shown you above, Bolton really provides more than either of these towns. I sympathise largely with the remark of Mr. Donald Mackenzie, of Edinburgh, that the "sinking fund contributions profoundly affect the financial position when contrasting the various municipal undertakings in reference to depreciation"; and that is why we have not in fixing our depreciation taken any note of the sinking fund requirements. I admit that we make the sinking fund payments out of this full depreciation, and I don't see any particular reason why we should not do so. I think it likely, when it is legally practicable, that I should agree with Councillor Walmsley (chairman of the Finance Committee), whose paper is entirely based on the idea of a 50 or 60 years repayment period, which ought to be kept independently of the depreciation charged—for the latter can be reduced accordingly. It is to be hoped this last opinion will take off some of the keen edge of your "startling discovery," for I take it we now, in effect, do what Mr. Walmsley would have us adopt under his two separate headings."

The Bolton paper also gives a quotation from the *Journal of Gas Lighting*, but with this we will not trouble our readers, inasmuch as, in our opinion, no journal is more conspicuous for selecting its phrases with regard to technical undertakings than the one quoted—it is merely an advocate.

INSTITUTION OF ELECTRICAL ENGINEERS.

At the ordinary general meeting of the Institution on Nov. 26 the following were the candidates balloted for:

Members.—R. W. Frazer, Anglo-Portuguese Telephone Company, Lisbon, Portugal; W. M. Horsfall, 22, Hackins Hey, Liverpool; J. F. Kelly, Ph.D., 284, West Housatonic-street, Pittsfield, Mass., U.S.A.; F. A. C. Perrine, Pittsfield, Mass., U.S.A.

Associate Members.—W. J. Abel, 99, Waterloo-crescent, Nottingham; S. F. Blyth, Electricity Works, Great Yarmouth; F. B. Cramer, 17, De Vere-gardens, Kensington; E. N. Greaves, Corporation Electricity Department, Bradford; H. H. R. Green, Engineer's Department, St. James's-gate Brewery, Dublin; E. Heitmann, Stanley Instrument Company, Great Barrington, Mass., U.S.A.; T. P. Pask, Natal Government Railways, Pietermaritzburg; F. S. Robertson, Siemens Laboratory, King's College, W.C.; E. T. Steinthal, 1B, Cooper-street, Manchester; J. J S. Stuart-Fox, Western Telegraph Company, Rio de Janeiro, Brazil; G. E. Unbehaun, 61, Booth-street, Balmain, Sydney, N.S.W.; C. J. Wawn, care of Municipal Council, Shanghai, China; L. B. Woodworth, P.O., Cleveland, near Johannesburg, Transvaal; A. Wunderlich, 21, Coleraine-road, Blackheath, S.E.

Associates.—F. I. Bennett, Foden Bank, Macclesfield; J. Bradwell, 37, Park-avenue, Southport; A. E. Carr, P.O. Box 84, Germiston, Transvaal; G. E. Ensor, C.S.A.R. Telegraph Department, Pretoria, Transvaal; A. Innes, 24, Butterfield-street, Richmond Hill, Leeds; R. W. Newman, Government Irrigation Works, Thebus, Cape Colony; J. Purvis, 120, Durants-road, Ponders End, N.; J. Stavers, 24, Willow-road, Hampstead, N.W.; C. White, 24, Wolseley-road, St. Helens, Lancashire; A. Wright, Corporation Electricity Department, Barnsley, Yorkshire.

Students.—A. Clark, care of Messrs. Robey and Co., Lincoln; S. J. Eardley, The Grove, Alfreton, Derbyshire; C. K. Fitzherbert, Faraday House, Charing Cross-road, W.C.; C. H. Fox, The Quarry, Ilfracombe, Devon; J. A. Galiano, 34, Cranley-gardens, Kensington, S.W.; W. L. Harliss, The Gables, Boston, Lincolnshire; W. E. Hean, 64, Clifford-street, Glasgow; A. H. Huddart, Penrith House, Breakspears-road, Brockley, S.E.; N. Neill, 26, Byron-road, Sheffield; G. E. Newill, 48, Wheeleys-road, Edgbaston, Birmingham; C. M. Pletts, Chester House, Brockley, S.E.; G. F. Sills, 44, Burnt Ash-hill, Lee, S.E.; F. H. A. Thoday, Langtons, Hornchurch, Essex; C. F. Waddington, Lindum House, Armley, Leeds.

APPOINTMENTS VACANT.

Engineering Assistant, used to tramway work, Finchley Urban District Council, £175 per annum. Application by Dec. 3.

Shift Engineer, Tunbridge Wells, £100 per annum.

Assistant Electrical Engineer, Sanitary Commissioners, Gibraltar. Salary, £200 per annum. Applications by Dec. 16. See advertisement in former issue.

Engine-Room Attendant. Salary 35s., rising to £2 per week. Particulars from the Secretary, South-Western Polytechnic, Manresa road, Chelsea, S.W.

Tramways General Manager, Bolton. Salary, £500 per annum. Dec. 4.

Traveller with connection amongst buyers of arc lamps and switchboards, Box 808, *Electrical Engineer* Office.

Junction Box Fitter, used to fitting house fuse boxes, Box No. 909, *Electrical Engineer* Office.

Cable Jointer, York Electric Lighting Station, Dec. 7. See advertisement in last issue.

Electrical Draughtsman (temporary), Metropolitan Asylums Board. Salary, £2. 10s. per week. Dec. 5.

Surveyor and Electrical Engineer, Boston. Salary, £300. Dec. 18.

Switchboard Attendant, Motherwell. Salary, 25s. per week.

Draughtsman. Apply to Box 519, G.P.O., Manchester. See advertisement.

Engineer. Apply to Box 402, *Electrical Engineer* Office. See advertisement.

Shift Engineer. Salary, 30s. per week of 56 hours. Apply to the Borough Electrical Engineer, Electricity Works, Gillingham, Kent, by Dec. 7. See advertisement.

Works Superintendent, Dublin; salary, £200 per annum. Shift Engineer; salary, £117 per annum. Sub-Station Foreman; wages, 45s per week. Dec. 9 See advertisement.

Shift Engineer, Fulham. Salary, £104 per annum. Dec. 12. See advertisement.

Clerk and Accountant, Portsmouth Telephone Department. Salary, £90 per annum. Dec. 14. See advertisement.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 18s. 6d. New Volume, January to July, 1903, now ready.*

PRINCIPLES—LAWS.

We are living in a world of changing ideas. Quite recently, so to speak, our seemingly settled opinions have been knocked on the head by the introduction of the concept electricised corpuscles. The *Engineer* in its last issue gravely attacks the doctrine of the conservation of energy. Of course, in this attack the most is made of the peculiar properties of radium, many of which cannot well be explained by ruling theories. Mr. Cowan in his presidential address at Manchester said: "It is a matter of great regret that the principles—does he mean laws?—of economic science have not been only ignored, but rejected by the large majority of those who have contributed during the last few months to this discussion." Certainly, we are often struck by the exceedingly great dogmatism shown by the lesser lights of science, who usually speak of "laws" as if the laws ordinarily known to science are infallible and beyond the realms of discussion. On the other hand, the most advanced thinkers more often speak of these laws as promulgated as the best working hypotheses at present known. They are not averse to change, or to put aside a so-called law, if investigation proves that that law does not cover all known cases. All they ask is that before one law is put aside a better working hypothesis shall be formulated. There seems to be a very great tendency in recent years to devise theories rather than to pile up facts. A new investigation gives a funny result, and, of course, the investigator imagines he has done all that is to be done in that particular direction, and found out all that is to be found out; so he, or probably his interpreters, desire to modify some law which has hitherto been accepted. The probability often is that further investigations may tend to introduce new facts, and in the end the whole of the results obtained may be found to conform to recognised laws. On the other hand, they may not. But whichever be the case, there is not the slightest reason to hurry. It would take far more to break down the very excellent working hypothesis, conservation of energy, than the few facts hitherto determined with regard to radium.

When we come to discuss Mr. Cowan's statements we are on still more ticklish ground. We absolutely deny that any principles of "economic science" have been broken, because, in our opinion, none exist. Adam Smith, Bentham, Mill, Rogers, etc., each and all made certain premises, which, thrown into the syllogistic form, give logical and true conclusions These premises, however, were founded upon conditions they knew or imagined, hence applied to those conditions, and none other. Change the conditions you change the premises, and must inevitably change the conclusions. Will Mr. Cowan deny altered conditions? If not, he may be consistent, but his opinions are not worth much. Let us take one statement which perhaps shows his consistency, but which also shows his lack of real investigation into the matter. He says: "It is well known, and, so far as I know, universally accepted, that the relation between imports and exports is normally simply that of an equation."

That statement is incorrect as stated, and never has been universally accepted, and will not be because of its incorrectness. The one point not dealt with by Mr. Cowan, nor, we may say, by any single individual of all the so-called free fooders (not free traders—a thing which they are not), is that there is no trading business which ever existed, or will ever exist, be it of a nation, company, or individual, which does not have to account for savings or losses. An equation to denote this without an unknown and constantly varying factor to represent losses or savings is an absurdity, and it is

Digitized by Google

a simple disgrace to the intelligence of this country that such wild assertions can be made. That the masses take these assertions as gospel truth, thinking the speakers have really considered the question, is unfortunately a fact; hence the tendency to be governed not by truth, but by blatant dogmatism. Will Mr. Cowan tell us where a business exists that does not have to consider profits or losses, and tell us is it possible for any business not to have recourse—periodically, or, it may be, systematically, till all are gone and the business ruined—to savings in order to buy what is wanted. We are not now appealing to the intelligence of the land for or against Mr. Chamberlain's projects; we want to appeal to scientific men, who ought to be deep thinkers, to look more closely into a question of surpassing importance before they dogmatise on the subject.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

COMPOUND MOTOR.

SIR,—In the first answer to Question No. 632 of this week's issue I see the following: "For the same result can be obtained with a plain shunt motor of good design, by setting the brushes with such a forward lead as to maintain a constant speed through the influence of armature reaction." If such a remark as this is not a mistake, surely the answer should not be credited with full marks; or, if not an error in "A. D.'s" answer, it must be a printer's mistake, which I now beg to correct to "by setting the brushes with such a backward lead as to maintain," etc., as I am afraid a motor of 550 volts would not hesitate to flash across with forward lead; but, apart from this, the speed would be diminished as the load increased, and not raised.—Yours, etc., C. Y.

Nov. 30, 1903.

LIMITED LIABILITY, ITS ADVANTAGES, ETC.

SIR,—Referring to our pamphlet which you were kind enough to notice in a recent issue, will you please allow us to remind your readers who are sending for a copy of the same that full name and address should be enclosed. This has not been done in several letters, so that we are unable to forward on to them.

The pamphlet is sent, post free, on receipt of three stamps, to anyone enquiring for it.—Yours, etc.,

THE LANCASHIRE TRADERS' ASSOCIATION,
Central-buildings, 41, North John-street, Liverpool.

STEAM TURBO-GENERATORS.

SIR,—It would be an interesting contribution to the controversy at present proceeding in your columns on the relative merits of steam-turbines and reciprocating engines, if someone would explain the reasons which have induced the authorities at Blackpool to go in for reciprocating engines of the "high-speed self-lubricating" type for their present extensions, after using steam-turbines exclusively for so many years.—Yours, etc., TRUTH SEEKER.

ELECTRICAL PROSPECTS IN SOUTH AFRICA.

Probably no more opportune time than the present could have been selected for the issue of the voluminous and valuable report which has been prepared by Mr. Henry Birchenough, the special commissioner appointed by the Board of Trade to enquire into the present position and future prospects of British trade in South Africa. The exact position of electrical engineering in Cape Colony and the new dependencies of the British Crown in that country is to-day uncertain in the sense that the amount of work likely to be obtained by English manufactures and the prospects of expansion in this particular field in the future are a practically unknown quantity. The present report supplies much of this important information, and we think the following notes which we have abstracted from its pages will go a long way to help manufacturers to realise the really excellent prospects they have in South Africa, which offers what is at present practically an undeveloped and profitable market for their wares. In certain localities, notably in the Johannesburg district, England is already doing well in the obtaining of large and valuable orders for electrical machinery and plant of all descriptions. In others she is lamentably behind both the Continent and America. This should not deter, but should rather spur on British manufacturers to enter into competition with their pushing foreign contemporaries. How this may best be done is shown in the document under review, and home firms will be well advised to closely study the points set out in the report wherein it is believed British manufacturers more often than not fail in their rivalry with firms of Continental and American origin.

Mr. Henry Birchenough, the special commissioner appointed by the Board of Trade, arrived in Cape Town from England on Jan. 20 this year, his stay in South Africa extending over a period of 15 weeks, during which time he had the opportunity of visiting practically all the important industrial and commercial centres of the Colonies, including Johannesburg, Bloemfontein, Durban, Kimberley, and Port Elizabeth. It must be remembered that at this time the commercial situation in South Africa was still in an abnormal and transitional state, but this temporary depression is now rapidly giving place to a more normal and healthy condition of affairs. But to keep to our subject, we find that among the list of new openings for trade the commissioner mentions electric lighting and traction, particularly in connection with municipal enterprise, while the substitution of central electrical power stations upon each mine or group of mines in place of the present scattered plant will largely increase the demand for electrical machinery—such as generators, motors, electrically-driven pumps, etc. The use of electrical power, especially in the deep-level mines, where it possesses many advantages over compressed air, is quite certain to take an enormous extension during the next few years, and deserves the closest attention on the part of British manufacturers. In this connection it is the general opinion of engineers upon the Rand that the future belongs to the three-phase alternating system because of its greater flexibility, and not to the continuous-current system. The commissioner was repeatedly informed that one of the principal reasons why British engineers have fallen behind in the competition for electrical work on the Rand is their conservative adhesion to the continuous-current system. Commenting on the activity of municipal enterprise in the country, the report mentions the large scheme for electric lighting, power, and tramways which has been decided upon by the Johannesburg Corporation, the estimated outlay on which is about £1,240,000, but it will probably exceed that sum. In regard to private enterprise, it is shown that the total estimated value of the electric light and power generating plant installed by companies is about £315,000, representing 37 steam-engines, eight other prime movers, and 31 boilers. It appears that imports of merchandise into South Africa are largely made by Americans. In 1901 the total value of American imports was £2,640,193, as compared with £4,429,839 in 1902, an increase of 67 per cent. Among the principal imports was electrical machinery of all kinds.

A few points in American or foreign business methods which are said to give those who adopt them an advantage in the market may be conveniently noted here. First, Americans adapt their manufactures to the precise use and work which is demanded of them; then they understand how large and important a part freight plays in the landed cost of machinery, especially upon distant inland mining fields, so whenever they can they lighten weights. It is impossible to insist too strongly upon the fact that the question of a close and untiring study of the special circumstances and requirements of a market which is constantly changing and developing, goes down to the very root of efficiency in competition. It is the one point of all others

Digitized by Google

to which British manufacturers ought to give their closest attention.

Another point in favour of foreign firms is that wherever they have reasonable expectations of being able to build up a trade, both Americans and Germans readily incur large preliminary expenditure; in other words, they are willing to sow liberally in order that they may reap. Again, Americans furnish their customers with far more information than British manufacturers. Their idea is that manufacturers should create a demand in order to supply it. As an instance, we may quote the following passage: "The borough electrical engineer of the city of Durban showed me quite a library of pamphlets upon all the new developments of electrical science sent to him by American firms, cleverly illustrated with their own apparatus, and giving all kinds of useful information as to working costs, results of the experience of users, and so on. Such information is invaluable to engineers in sparsely-populated colonies, who have only the opportunities which books afford them of keeping abreast of scientific progress in their own departments. This is no isolated case, nor is it confined to electrical companies. The heads of other public departments in all the Colonies showed me proofs of the remarkable and highly intelligent enterprise of American manufacturers in this direction. It is easy to imagine how great the temptation is to engineers to place orders with firms which render them so much assistance, and, in a sense, relieve them of so much responsibility."

In the drawing up of specifications, in prompt delivery, in standardisation, in better finish, in superior packing, in producing on a large scale in order to sell cheaply, in representation, and in price—in all these points the American competitor is said to greatly excel his British *confrère*. One other point may be mentioned—viz., foreign traders do not give their customers in the Colonies better terms than British traders except in the mining industry, where they appear to be more accommodating and liberal. The following suggestions as to the means by which foreign competition may be effectively met have been gathered from various sources, and are offered for what they are worth: A clearer realisation of the great and expansive future of the market; the employment of far more energetic and less conservative methods of business; a careful study of local conditions and requirements with a view to the closer adaptation of machinery to the particular work that is demanded of it; direct representation in Johannesburg; wide discretion being given to representatives in quoting prices for competitive tenders; British firms should be represented by British agents; the ordinary mines' terms should be frankly accepted, and business should be financed from the British side; prompter delivery and a closer adherence to contract dates; larger local stocks of standard types of machinery, of fittings, and spare parts should be kept; standardisation, wherever possible, and an extension of the practice of working to gauge should be effected; more attention should be paid to details and to "selling points"; cheapening of production; more brain work should be put into designs; the high standard of British workmanship and British material should be carefully maintained; and British engineers should be trained to fill a larger number of the "order giving" posts on the mines.

We now come to the supplementary reports, which follow the general information and deal with the prospects of trade in certain specified districts. The first that arrests our attention is that by Mr. William Tosh, inspector of machinery in the Johannesburg district, where, as we have stated, British manufacturers have succeeded in obtaining the greater bulk of the work. Thus, in electrical machinery Great Britain supplied 83 per cent. of the generators in use, as against 14 per cent. by Germany and Belgium and 3 per cent. by America. Again, 72 per cent. of the motors came from this country, against 14 per cent. from Germany and Belgium and the same proportion from America. Arguing from the point of view, presumably, that England should have the whole of the business in her own hands, the reporter gives the following principal reasons for the success in obtaining orders of the other countries mentioned: First, on account of the large stocks held by German representatives; and, secondly, because the efficiency of the foreign-made article is slightly higher than the British; and he urges British manufacturers to augment their local stocks and increase their energy. Another report, by Mr. C. B. Pattrick, inspector of machinery in the Krugersdorp district, deals extensively with electrical machinery. In this district this business is principally in the hands of the Germans and Americans. Mr. Pattrick states that the big three-phase generators and motors of leading Continental make leave nothing to be desired. Explaining the advantages of a three-phase, high-pressure plant, he says that three men can run a large plant, which, if continuous current low tension, would require from seven to nine men to keep it in order. On one mine in the Krugersdorp district the three-phase current (2,000 volts) for the mine pumps and lights is conveyed down the shaft by naked wires, encased in a wooden cupboard which extends the full length of that portion of the shaft which is traversed by the cable, and effectually prevents any person from coming into contact with them. This is found to be more satisfactory than the lead-sheathed cable in general use. In passing, the reporter calls attention to the importance of good insulation. As the three-phase high-tension machinery is, doubtless, the plant of the future for South African mines, the following points are instructive: 'Bus bars should be about 10in. apart and not 6in., as frequently placed, because in damp weather the current will arc over a 6in. space. Fuses should be well out from the board, and in a horizontal position, as otherwise they set up arc between overhead 'bus bars. In this country, where thunderstorms are so extremely severe, a space of at least 6ft. to 8ft. clear should be allowed behind the board. The Siemens high-tension glass-enclosed fuses are the most satisfactory, as they are all made to absolute standard. Insulated pincers for drawing them should always be at hand. Mine motors and others in damp places should have liquid starting resistances, as ordinary rheostat switch coils corrode with damp. The horn lightning arrester is beyond all comparison the best. For shop motors, those starting with a resistance work more satisfactorily than those with short-circuiting clutch, as the clutch is liable to get worn and not make good contact, often causing the rotor to burn.

In concluding this article, we cannot do better than reproduce a statement supplied by Mr. Holtby, consulting electrical engineer, upon the present state of the electrical machinery market upon the Witwatersrand. His remarks, although dealing with a specified locality, may be taken as applying to British South Africa generally, and are of great importance. The following is the report in question: "The supply of electrical machinery for gold-mining purposes is at the present mainly in the hand of American and Continental firms with perhaps one or two slight exceptions, and is due probably to the following reasons: (*a*) America and Germany in the order named were the first to realise the extensive field for their electrical manufacturers in this country, and the case of America was greatly helped by the fact that many of the consulting mining engineers on the Rand were Americans or men who had worked on the American goldfields and had become accustomed to American machinery and appliances. Germany was mainly successful through one large firm, which established a direct representative in Johannesburg, and also carried stocks of appliances. This firm also obtained control of the Brakpan power line, which put them in a strong position, and it was natural that machinery suited for this power line should be supplied by them; especially so in cases where mines used power from the line. This firm also rented suitable motors and apparatus, etc., to the mines. Another strong reason was that the Continental and American manufacturers were the first to see the general suitability of three-phase alternating-current machinery for mining purposes, and consequently were in a position to meet the first demand from the Witwatersrand, and when once a particular system of transmission is installed, there is a tendency to continue it. Machinery used on a group of mines can thus be interchangeable, less spares are required, etc. Another reason was that the price of American electrical machinery was lower than that of any other country before the war, also the time asked for delivery was in many cases only two-thirds of that asked by British firms, this being, no doubt, due to

Digitized by Google

the better standardisation of their patterns. In passing, we may note the importance of standardisation. It is undoubtedly of great importance to be able to cable for spare parts of machinery, and it is only where standardisation is carried to considerable perfection that this can be done. British manufacturers have been, with a very few exceptions, very feebly represented here, and, instead of opening a branch, have been quite content to allow general engineering firms to represent them. In many cases the engineers of the firms in question have had little or no electrical knowledge, the result of which has been the success of the more pushing representation. (*b*) I would suggest that British firms open branches and not mere agencies in Johannesburg, carrying stocks of cables, motors, and general fittings for same. Samples of large pieces of machinery might, perhaps, also be carried. This would mean that special men able to explain technicalities would be in charge. Great care should be taken that the goods offered are suitable for mining operations. A considerable amount of electrical machinery has been sold that is totally unsuited for underground work. This is due to want of proper attention to the conditions under which mining is carried on here, and to the fact that electrical mining machinery has only comparatively recently been made in England. Further, instead of making new patterns developed by mining specialists, stock patterns have been slightly altered, and then considered at suitable, which is a very grave mistake, for in mining reliability in use is of utmost importance. Much of the trouble experienced in the past with electrical machinery underground can be traced to apparatus only suitable for above-ground purposes. (1) I should say that the actual workmanship bestowed upon English machinery is better than either American or Continental, but this avails nothing if the fundamental principles are missed and the types sold are unsuitable and not specially adapted for the work to be done; (2) prices are higher in the cases of British and Continental electrical machinery than in those of American, probably for the reasons mentioned under (*a*)—namely, standardisation; (3) I do not think there is much superiority of one country over another in efficiency. Probably American is lower in some instances than either that of England or the Continent. No doubt deep-level mining will bring about many changes in machinery used. In all probability in many deep shafts there will be intermediate hoists, which will probably be electrically driven. Manufacturers will do well to pay close attention to these hoists. Probably the power required will range from, say, 250 h.p. to 1,000 h.p."

Mr. Holtby concludes by presenting two general specifications—one for an electric hoist to be used in the incline at the bottom of a vertical shaft, and the other for a combined motor and pump. They are worthy of study.

THE TESTING OF ELECTRIC GENERATORS BY AIR CALORIMETRY.

BY RICHARD THRELFALL, M.A., F.R.S.

The following is an abstract of a most interesting paper read before the Institution of Electrical Engineers in London on Thursday, Nov. 26. It describes a method of measuring the actual losses in an alternator which is coupled to an engine. The author points out that in a number of cases it is impossible to measure the brake horse-power of engines driving alternators. For this reason he devised and experimented with a means of directly measuring the heat losses in the alternator. To do this he enclosed an alternator of 300 kw. capacity in an air-tight non-conducting casing and passed air through at a measured rate. He then ascertained the temperature of the air entering the case and that of the air leaving. The difference between these temperatures, together with the quantity of air passed in a second and the specific heat of the air, enabled him to determine the rate at which power was being wasted in the alternator. In the first part of the paper Prof. Threlfall describes in detail the way in which he measured the volume of air which was passing out of the air-tight case. The velocity at various parts of the tube was determined by Pitot gauges. In order to keep down radiation losses from the case, the air inside was kept at about the same temperature as the air in the engine-room. After the alternator experimented on had been encased, the incoming air duct was connected through the wall of the engine-room to the atmosphere. A fan in the outlet driven by an electric motor then was set to work, and it was found that a steady condition of affairs was reached in a few hours. In the first experiment a resistance frame was used as the source of heat inside the case, but the alternator was kept running in order to give the same circulation of air as in the later trials. When by electrical measurement 37·8 kw. were being wasted in the resistance frames, the heat carried out by the air stream was equivalent to 40·865 kw. Another test proved that the heat due to windage and conduction along the engine shaft was 2·066 kw. This reduced the error in the determination of the power to 2·51 per cent. In a subsequent trial under the same conditions a negative error of 1·77 per cent. was found. Tests were then made on the alternator, with the results given in the following table:

Date. 1902.	Kilowatts.	Magnetising current.	T.C.° Inlet.	T.C.° Outlet.	Inlet + Outlet / 2.	Mean temperature of casing, back and front.	Heat supply measured. Kilowatts.

From these figures the efficiency of the dynamo works out at full load to be 89·05 per cent., excluding the loss of heat in the exciter itself, which was outside the case. As the author points out at the conclusion of his paper, this method also allows certain of the losses to be independently determined. His experiments show that it can be depended upon to give the losses accurately to within 2 or 3 per cent., which means that the efficiency can be determined with a very high degree of accuracy. The casing used to surround the alternator was built up of ½in. grooved and tongued boarding, which was afterwards covered over with tinfoil. It is interesting to know that the total works cost for labour and material for setting up the testing apparatus was only £19. 9s The information given as to the best methods of measuring the flow of air, etc., will be of great service to any engineer adopting the method for future tests.

Discussion.

Mr. W. B. Esson, who opened the discussion on the above paper, said that, so far as he knew, the method of testing therein described was quite novel, and he was glad to see that it gave results which might have been expected. It, however, required a good deal of expert knowledge to get accurate results with it, and personally he had regarded with some suspicion the results he had obtained until he had had a great deal of experience in this way of testing. He thought it tested the experimenter just as much as it tested the apparatus. Coming to the question of the iron loss at no load and at full load, he found that the author gave the iron loss at full load to be something like 10 per cent. of the output of the generator, while at no load it was approximately 7 per cent. From some previous work on the subject he was inclined to believe that this loss was in the field poles of the generator and not in the armature core, and that the difficulty could be got over by completely laminating the poles.

Prof. Threlfall interposed to say that in the machine used by him the poles were only partly laminated, and that the loss was in the poles.

Mr. Esson said it would seem to show that merely laminating the tips of the poles was not sufficient to get a very high efficiency. He would point out, in conclusion, that Mr. Blathy, some time after he (Mr. Esson) had made his experiments, found the very same thing in testing continuous-current machines.

Dr. R. T. Glazebrook announced that they were working with the Pitot-tube method of measuring at the National Physical Laboratory. Prof. Threlfall's statement, that the momentum of the impinging air was reduced very nearly half, bore out the theory of Lord Rayleigh; and Dr. Stanton, at the National Physical Laboratory, has arrived at practically the same

Digitized by Google

result. The important point was that it had been shown by these experiments—which were soon to be described elsewhere—that the Pitot tube was a very accurate instrument for measuring streams of air. With regard to the calorimetrical result, he gathered that the efficiency of the dynamo used by the author was measured with a considerable stream of cool air coming in. He therefore assumed that the temperature of the whole machine was lower than would obtain in actual practice. This might have an important bearing on the results.

Mr. W. M. Mordey pointed out that some of the old methods of working, even if correct, required at least as much expert attention as the method described by Prof. Threlfall. He was particularly interested in the author's references to the measurement of the air, because he was just now considering the question of the measurement of the quantity of gas passing through very large pipes for the supply of big gas-engines. He would ask the author whether the curve of air velocities was taken on a vertical cross-section or a horizontal? There was a considerable difference, he noted, between the values of the upper half of the curve and the lower half. He also asked what precautions were taken to see that the inside surface of the pipes to which this method was applied did not vary the result? The Pitot method would probably find its greatest usefulness in works, but the principal objection to it was that it must necessarily take a considerable time to get any reliable observations. He wanted to know how long it would take to ascertain the efficiency at various loads of a large machine taking from 10 to 12 hours to reach its full temperature, and again, was it possible to measure the indicated horse-power accurately with small loads when the engine was running light?

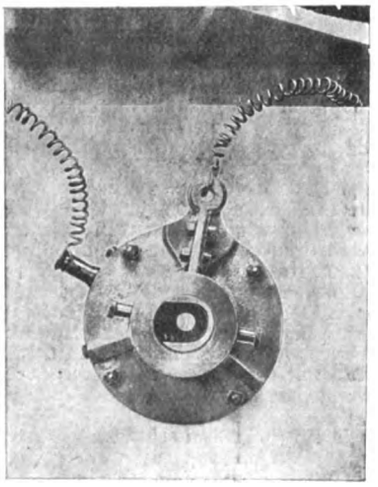
Prof Threlfall, in his reply, said a great deal had been said in the discussion about the results of the tests, but he would point out that the first object of the paper was to bring to the notice of the Institution the method itself. He hoped at some future time to be able to present the results to the society. Mr. Esson seemed to be scared by appearances of difficulty in using this method, but the clear presentation of the subject rendered this unavoidable. He could assure them that it was not necessary to be so minute as appeared from the account given in the paper. The chief difficulty with the method was in measuring the electric output with accuracy. The measurement of the air was not he thought difficult. He should be extremely sorry if they were to go away with the idea that this method was a complicated one, or that it contained pitfalls for engineers. As to the time occupied in taking measurements, it would be about four to six hours in the case of a 300-kw. machine after steadying the load. This allowance of time would give consistent and accurate results within 1 per cent. But with the sacrifice of about 2 per cent. accuracy the measurements could be made with this system in something like an hour. Replying to Dr. Glazebrook, he stated that the air was heated up to the temperature obtaining in actual practice. The diagram of air velocity distribution was through a horizontal diameter, and was only correct for the velocities given. The temperature of the air leaving the generator was estimated while in turbulence. He never detected the slightest difference in temperature. With regard to Lord Rayleigh's results, he cordially agreed with all Dr. Glazebrook had said. He would reserve his remarks on the question of the measurement of air and gases for another occasion, when he should have an opportunity of dealing entirely with that part of the subject.

A hearty vote of thanks was accorded the author.

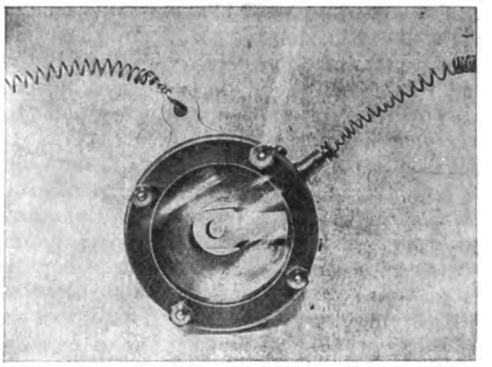
TRADE NOTICES AND NOVELTIES.

Electric Ignition.

Electrical apparatus for exploding the compressed charges in automobile engines has been largely developed during recent



years. One step in advance is the substitution of mechanical interrupters for the magnetic trembler previously used with induction coils. The mechanical apparatus for making and interrupting the circuit is more reliable and more under control. It allows also of the time of ignition being regulated easily. The illustrations herewith are of a new wipe contact circuit breaker put on the market by Messrs. L. Rene and Co., of 6, Snow-hill, E.C., and exhibited by them at the recent National Cycle Show at the Crystal Palace. Besides being adapted to motor cycles, the contact breaker is standardised



for two and four cylinder motorcars. The apparatus is made both in steel and aluminium.

Catalogues and Pamphlets, Etc.

VIEWS AND USES OF WILLESDEN PAPER AND CANVAS. Willesden Paper and Canvas Works, Limited, Willesden Junction, London, N.W.—These products are waterproof, rot-proof, and time-resisting, and we are informed that the firm have drain-pipes in use at their works (made from this paper) which were put into the ground 30 years ago. The pamphlet is illustrated with fine views of important buildings where this material is used as roofing or under slating.

VULCANISED FIBRE. Mosses and Mitchell, 68-71, Chiswell-street, E.C.—The advantages claimed for these valves are that their immersion in cold or boiling water only gives them more flexibility. They resist the action of oils, so destructive to rubber, and they do not expand in diameter, so require no cutting round the edges to free them from nuts, guards, etc.; also that they work equally well with a slow as with a fast action pump, and are as efficacious with a dead lift as with a bending or cup guard.

LABOUR AND TIME-SAVERS Illustrated. Beanland, Perkin, and Co., School Close Works, Leeds.—Describes several patterns of new single and double hack saws, a portable electric hack saw for shipyards, engineers, iron, and girder merchants, portable rail saws, the Britannia trimming and mitreing machine, a new improved hand screwing machine for engineers, smiths, wheelwrights, etc.

CABLES. W. T. Glover and Co., Limited, Manchester.—An illustrated post card showing the cable-laying at Stalybridge.

EIGHT-POLE DYNAMOS AND MOTORS. Union Electric Company, Limited, 151, Queen Victoria-street, London, E.C.—These machines cover a range from 100 h.p. to 500 h.p. at the usual standard voltages, and they are constructed with a large range in speed to suit the various requirements of dynamos and motors of such large power. Each size of magnet frame and armature can be completed in five different mechanical outfits, the simplest being suitable for forcing on to the engine, pump, or other shaft, and the most complete being that with three bearings mounted on a box bed-plate, and arranged for either rope or belt driving. The armature windings consist all of shaped bars sunk in accurately fitted and smooth surfaced slots in the cores. This type of machine allows for ample ventilation, and therefore large output weight for weight.

AUTOMATIC TIME SWITCHES. Illustrated. Vandam, Marsh, and Co., Limited, London, Birmingham, Manchester.—Fully describes a large variety of these instruments.

HOWARD TROUGHING. The Howard Conduit Company, Trafford Park, Manchester.—The company have chosen an illustrated postcard to draw attention to the advisability of relaying old rubber cables in their troughing instead of scrapping them.

PATENT AUTOMATIC FUEL-SAVING APPARATUS (CO_2 RECORDER) "Ados." Sanders, Rehders, and Co., London and Manchester.—We are informed that during the last 12 months this ingenious apparatus has found great favour amongst central electricity stations and other large works, several having now installed as many as five and six recorders. This proves the great usefulness of this recorder as a means of checking combustion in boiler furnaces, and thus effecting considerable economy in the coal bill.

PERSONAL.

The Eastern Telegraph Company, Limited, and the Eastern and South African Telegraph Company, Limited, announce that Mr. George Draper, who has been secretary of the two companies since their formation, retires from office with a pension on 1st prox. Mr. A. R. Hardie formerly the accountant, has been appointed secretary.

The Exeter Council have granted £105 to Mr. H. D. Munro, the city electrical engineer, in respect of his special services in connection with the extension, designing, erecting, and equipping the new power station, and have increased his salary to £350 per annum.

The Sunderland Tramways Committee have appointed Mr. A. M. Dayson, at present assistant manager and engineer of the Sunderland system, as manager to succeed Mr. Harry England, subject to the approval of the Council.

The Newcastle Tramways Committee have resolved to increase the salary of Mr. Rossignol, general manager, from £750 to £850, and rising £50 per year to £1,000. The salaries of the car-sheds manager and the chief clerk are also to be increased.

FORTHCOMING EVENTS.

FRIDAY, DEC. 4.

Institution of Civil Engineers (Students' Section).—At 8 p.m., ordinary meeting. Paper: "Artificial Draught as applied by Fans to Steam Boilers," by Mr. W. H. A. Robertson.

Junior Institution of Engineers.—At 8 p.m., ordinary meeting. Paper: "Recent Developments in the Construction and Working of Gas-Engines," by Prof. D. S. Capper.

SATURDAY, DEC. 5.

Glasgow Scientific Society.—At 7.30 p.m., ordinary meeting. Paper: "Superheat," by Mr. W. H. Booth.

MONDAY, DEC. 7.

Society of Arts. — At 8 p.m., Cantor lecture: "The Mining of Non-Metallic Minerals," by Mr. Bennett H. Brough. (Lecture III.)

TUESDAY, DEC. 8.

Faraday Society.—At 8 p.m., ordinary meeting. Papers: "Total and Free Energy of the Lead Accumulator," by Mr. R. A. Lehfeldt, D.Sc. (discussion adjourned); "Bitumen in Insulating Compositions," Part I., by Mr. D. A. Sutherland, F.I.C., F.C.S.; "Notes on Aluminium Welding" (illustrated), by Mr. Sherard Cowper-Coles; "Electrochemical Installation at the Borough Polytechnic Institute," by Mr. F. M. Perkin, Ph.D.

Institution of Electrical Engineers (Glasgow Section).—At 8 p.m., ordinary meeting. Paper: "The Education of an Electrical Engineer," by Prof. F. G. Baily.

Institution of Civil Engineers.—At 8 p.m., ordinary meeting. Paper to be further discussed: "On the Distribution of Mean and Extreme Annual Rainfall over the British Isles," by Mr. Hugh Robert Mill, D.Sc., LL.D. Succeeding papers: "Deposits in Pipes and other Channels Conveying Potable Water," by Prof. J. C. Brown, D.Sc.; "The Purification of Water Highly Charged with Vegetable Matter, with special reference to the Effect of Aeration," by Messrs. O. Chadwick, C.M.G., and B. Blount.

WEDNESDAY, DEC. 9.

Institution of Electrical Engineers.—At 7 for 7.30 p.m., annual dinner, Grand Hall, Hotel Cecil.

Institution of Civil Engineers.—At 2.15 p.m., students' visit to the locomotive works of the North London Railway at Bow-road. Train, 1.40 p.m. from Westminster Bridge Station.

Society of Arts.—At 8 p.m., ordinary meeting. Paper: "Furnaces for Jewellers' Work," by Mr. H. H. Cunynghame, C.B.

THURSDAY, DEC. 10.

Institution of Electrical Engineers.—At 8.p.m., Gilbert Tercentenary Commemoration. Presentation to the Borough of Colchester. At 8.15 p.m., ordinary meeting. Papers: The Slow Registration of Rapid Phenomena by Strobographic Methods"; "'The Ondographe' and 'Puissancegraphe'" by Mr. E. Hospitalier; and (time permitting) "On the Magnetic Dispersion in Induction Motors, and its Influence on the Design of these Machines," by Dr. Hans Behn-Eschenburg. (Dublin Section).—At 8 p.m., ordinary meeting. Paper: An Experimental Study of Stationary Electric Waves, with special reference to the Phenomena of Electric Resonance," by the Very Rev. Monsignor Molloy, D.D. (Students'-Section).—At 2 p.m., visit to the Incandescent Lamp Company's Brook Green Works, Hammersmith.

FRIDAY, DEC. 11.

Tramways and Light Railways Association.—At 8 p.m., inaugural meeting. Address by Mr. Atherley-Jones, K.C., M.P., on "Protection in Special Relation to Tramway and Light Railway Enterprise."

North-East Coast Institution.—General meeting at Newcastle-on-Tyne.

Physical Society.—At 8 p.m., at the Royal College of Science. Papers: "A Method of Mechanically Reinforcing Sounds," by Rev. T. C. Porter; "The Simmance-Abady 'Flicker' Photometry," by Messrs. Simmance and Abady; "Exhibition of a Conductometer," by Mr. M. R. Appleyard; and "A Model to Illustrate Various Properties of Wave Motion," by Prof. L. R. Wilberforce.

SATURDAY, DEC. 12.

West Hartlepool Scientific Society.—At 7.30 p.m., ordinary meeting. Paper: "Mr. D. B. Morrison's Scheme for the Advancement of Apprentices." by Mr. Wm. Kennedy.

Glasgow Scientific Society.—At 7.30 p.m., ordinary meeting. Paper: "Steam-Turbine Machinery," by Mr. Arthur A. Wynne, M.A.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

641. Show clearly how to calculate from the indicator card the water used per stroke per indicated horse-power in condensing and non-condensing engines.—G. W. S.

642. A battery of Tudor accumulators is connected in sections to the cell board by single-strand conductors No. 6 S.W.G., covered with hemp braiding. These conductors are burned into the leaden lugs of the accumulators, and are bare for about 1in. above them. Much trouble has been experienced through a very active corrosion which takes place in some cases even under the braiding. The bare parts have been scraped and repainted with "asphaltic black," but after a few weeks corrosion has again broken out. How can this be remedied?—A. B D.

ANSWERS.

Question No. 633.—Several car axles of an electric tramway have broken lately, all *exactly* in the same place—viz., ½in. inside keyway of gear wheel. Upon examination of these and other axles they show signs of being eaten away by electrolysis. Describe a remedy for this, also the action of the electric current upon the axles. The motor box is used for the earth return.

Answer to No. 633 (*awarded* 10*s.*).—This effect is very largely owing to the mud and other wet dirt which accumulates on the axle of the car, because this dirt would contain a good deal of mineral matter—composed of acids and bases—and known as salts in chemical language. These would not decompose electrolytically unless some circumstance gives rise to a difference of potential, which, however, need not be more than about three volts. We must, therefore, seek a resistance to the current in or near the axle and gear wheel, and as the current is large the resistance may be small, because the difference of potential it will cause, in volts, is the product of the resistance multiplied by the current in amperes, or $C \times R = E.M.F.$ The question seems to suggest that a large proportion of the current goes from the motor through the gear wheels, and that the gear wheel is not well fitted on to the axle of the car. If so, the whole of the trouble is accounted for in this way. Water and whatever it may hold in solution gets into the space between the gear wheel and the axle; probably a good deal lies in the keyway. This occasions rust, which is a non-conductor, and insinuates itself further and further, and so reduces the amount of clean surface of the body of the gear wheel and axle in actual contact. Now, considering the large current employed, we can easily understand that the decrease of conductive area between the wheel and axle occasions a difference of potential which would be quite enough to act electrolytically on the salts contained in the mud. The natural result of this would be to set free the acids, and these would immediately act upon the iron by dissolving it and so removing it. It will, of course, be readily understood that, although the gear wheel may be firmly fixed on the axle, there is a great difference between a good fit and a bad fit, and that whereas a really good fit would leave no room for liquid to creep in, a bad fit would leave a good deal of empty space, and mere capillary action would soon fill it with liquid. We have now only to remember that the keyway is the weakest part of the axle, and would, therefore, be the most likely to give way under a strain even if not weakened by the above electrolytic action. If the gear wheel is at all likely to be part of the electric circuit, it should be thoroughly and very closely fitted to the axle before the key is driven in, and the key should also be most carefully fitted for its entire length. After

Digitized by Google

being thoroughly well fitted the whole of the axle and the sides of the gear wheel might be well tarred with advantage to exclude moisture, and, if necessary, a further path might be provided for the electricity by placing a rubbing brush, similar to a dynamo brush, on the top of the car wheel rims and connecting this to the motor box so as to make electrical contact. This would reduce any difference of potential formed on or about the car axle, and so would almost for certain stop the tendency to electrolytic action there altogether with or without the suggested tarring; but the tarring would be an additional safeguard in any case, and well worth putting on. The suggested brush on the top of the wheels should not be put unless as a last resource, because, of course, it adds to wear and tear and maintenance troubles.—F. G. A.

Question No. 634.—Describe the theory and working of the Diesel oil-engine, and state wherein its advantages lie over a good make of ordinary oil or gas engine.

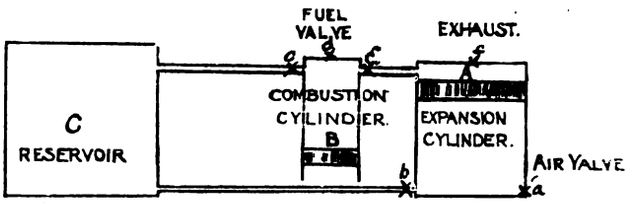
Best Answer to No. 634 (*awarded* 10*s.*).—The Diesel engine (not necessarily *oil* engine) is still so new that in any article on the subject a word as to its history cannot be amiss. Rudolph Diesel, of Munich, investigated the thermo-dynamics of the gas-engine, and from his purely theoretical and mathematical investigations was led to the conclusion that any great increase in efficiency in gas-engines working on the Otto cycle was physically impossible Continuing his investigations he was led to the theory of the ideal heat engine, and in his book, "The Rational Heat Motor" (Englished by Bryan Donkin, 1893), he develops this theory and designs an engine of 100 h.p. on this principle. This book was written and the engine designed before any attempts had been made to build a Diesel engine, as it is now called. The publication of the book led to much discussion. Many professors disagreed with the results obtained, but practical men were attracted by the possibilities of the new heat motor, and money was found to put theory into practice. By the energy of the Augsburger Maschinenfabrik, Sulzer Bros., Krupp, and others a laboratory was built in Augsburg, and experimental researches under the direction of Herr Diesel were started. The experiments, not unattended with physical danger, extended over several years ere a motor was built that could be put on the market. The perseverance and courage employed in these researches places them on a par with the greatest achievements of the fathers of engineering. The Diesel engine resembles ordinary oil and gas engines in that combustion takes place in the cylinder, but here the resemblance ceases. The ordinary internal-combustion engine fires the charge in the cylinder by external means (a gas flame or electric spark), whereas the temperature required for combustion in the Diesel engine is produced in the cylinder of the engine by the compression of air, and the combustible is not introduced until this temperature has been reached.

Diesel has laid down the following conditions for perfect combustion: 1. "The highest temperature of the cycle (temperature of combustion) must be produced before and independently of combustion by the compression of ordinary air, and not by and during combustion." It is well known that any gas is heated by being compressed. If the gas is compressed so quickly that it has no time to cool—*i.e.*, adiabatically—it naturally gets very hot, and any required temperature can thus be produced.

2. "Finely-divided combustible must be gradually introduced into the air when it is in the condition described above (very hot and at a high pressure) during the return stroke of the piston that has brought it into this condition. The combustible is added in such a way that its combustion causes no increase of temperature—*i e*, the heat caused by its burning just balances the heat lost by expansion. The process therefore takes place at a constant temperature—*i.e.*, isothermically. The combustion, after ignition, must be regulated by an external arrangement, so as to maintain the right proportions between pressure, volume, and temperature." In this condition, again, there is a considerable difference from the ordinary gas-engine, in which the combustible and air are mixed, compressed, and then fired, instead of (as in the Diesel engine) the air being compressed, and the combustible added and gradually burnt, being ignited by the heat of the compressed air.

3. "The third condition is that a proper weight of air must be chosen in proportion to the heat value of the combustible, the maximum temperature due to compression being so calculated that no artificial cooling of the cylinder walls is necessary to work and lubricate the engine." Here, again, is a departure from what was previously assumed correct. The amount of air required according to the above condition is much greater than the least quantity necessary for complete combustion. In gas-engines it has been considered that this latter quantity (the least amount required for complete combustion) gives the right mixture.

Though the Diesel engine is on the market, and many horse-power are in use and being built, the mechanical details of design are, of course, by no means fixed. A description of valve details, cams, etc., would, therefore, be out of place, and in describing the method of working only the successive operations will be given. Consider a simple engine of two cylinders—one for compression and combustion and one for expansion. (The sketch is merely diagrammatic, valves are indicated by crosses.) The piston, A, moves up and draws in air through the valve *a*; on the down stroke this is compressed and goes through the valve *b* to the reservoir, C. This is merely precompression, and must not be carried so far as to heat the air



unduly. The piston, B, during the down stroke draws in precompressed air, and on the up stroke (valve *c* being now closed) compresses it to the limit. The piston now moves downwards, fuel being admitted through valve *d* and burnt as described above. After moving down a small distance, the fuel supply is cut off, and expansion takes place. When B gets to the bottom of its stroke, A is at the top. The valve E is now opened, and the expansion continued in the larger cylinder, A moving down and B up. When A is at the bottom of its stroke, valve E shuts again, and on the next upstroke of A, the exhaust valve, *f*, opens, and the burnt gases are expelled. By having two cylinders, B, a combustion at each revolution is effected, instead of once in two revolutions.

As to the advantages of the Diesel engine over an ordinary oil or gas engine, first, the thermal efficiency is far higher than in any gas-engine. Though this high thermal efficiency is counteracted to some extent by low mechanical efficiency, due to the high degree of compression produced, the over-all efficiency is still greater than that of ordinary oil-engines, and may be expected to increase as experience is gained in construction. The engine is also cheap, as the cylinders are small, about one-third the size of cylinders of steam-engines of the same horse-power. Prof. W. C. Unwin, F.R.S., M.I.C.E., etc., in a report on the Diesel engine, says: "The Diesel petroleum motor is much better than any other petroleum motor. It has especially the following advantages: (1) Much greater economy of fuel, and, therefore, of the cost of working. It works with about five-eighths as much oil as petroleum engines hitherto constructed. (2) Much better regulation for varying load, and relatively to other engines, an increased economy of oil at loads less than full load. This is a very important point. (3) Greater facility for using oils of different qualities. (4) The diagrams (indicator) are of a better type than has been obtained before. (5) Nothing can be more convenient than the starting arrangements for the Diesel motor. (6) The two-stroke type has the very great advantage that nearly twice as much power is obtained as from a similar four-stroke engine of the same size and power. (7) I examined the exhaust of the engines, which is very clear and free from unburned oil. The Diesel engine can do with a lighter flywheel than explosion engines, and is therefore cheaper to construct in this respect. The two-stroke Diesel motor will have equal uniformity with a lighter flywheel."

Digitized by Google

The following table, which shows the cost per brake horse-power of various oil-engines and the Diesel engine, shows the cheapness of the Diesel motor. The figures are for cost at full load, and are taken from the oil-engine trials of the Highland Agricultural Society of Scotland, 1899, with the exception of the Diesel motor figures.

Name.	Horse-power.	Cost in pence per brake horse-power.
Crossley	16	0·650
Campbell	20	0·940
Stephenson	5	1·330
Blackstone	8	0·658
Tangye	17·5	0·636
Pollock	10	0·938
Cundall	8	0·782
Diesel	Any power	0·226

Much more might be written on the subject, but further information can be found in Diesel's book, "Rational Heat Motor" (Spon), and Diesel's paper in the *Zeitschrift Ver. Deut. Ingen.*, 1897, published also in the *Progressive Age*, December, 1897, and January, 1898. The pamphlets of the Diesel Engine Company also contain much information. I am indebted to all the above sources.—A. C. G. I.

Answer to No. 634 (*awarded* 7*s.* 6*d.*).—The Diesel engine was invented some eight years ago by Herr Rudolph Diesel. At first it could not be considered a success. Indeed, prophecy was of its ultimate failure, which prophecy has, however, proved entirely wrong. Subsequent to 1898 progress in improvement has been very rapid. Structural simplifications made in 1901, which increased the mechanical efficiency of the mechanism, but which at the same time reduced the cost of construction, have brought the design to something like finality in respect of the one type now chiefly built—viz., the vertical inverted marine type. One reason why the Diesel engine has suddenly become an important industrial factor is the discovery that the rawest and crudest oils and naphthas can be utilised in it with as great facility as can paraffin or other refined oils. The crude oils are as rich in heat of combustion as are the refined oils, and it only remained to discover the proper way to use them in order to reduce in a very large ratio the cost of generating mechanical horse-power from liquid fuel. The Diesel engine, which can consume petroleum refuse with little or no trouble, reduces the cost of a horse-power to less than that obtained by any but the best triple-expansion superheat steam-engine.

Theory.—Herr Diesel, after careful analytical and experimental study of the present forms of heat engines, and after comparing their cycles of operation with the ideal Carnot cycle, concluded that all existing engines were worked on defective principles, and that no radical improvement in their efficiencies could result until the principles of working were altered. Rationally following up this destructive criticism, he then proceed to construct a new process for utilising the heat of a combustible in the internal-combustion engine, and finally laid down the following conditions as being essential for the utilisation of the maximum amount of heat in the combustible. The following is the cycle of operations: first stroke takes in air alone; second stroke compresses this air to a high pressure (35 atmospheres = 500lb. on the square inch and a temperature of about 1,000deg. F); third stroke is the working stroke, during the first part of which the combustion of the fuel is carried on at constant pressure, which is determined by the amount of oil to be sprayed in, which quantity is controlled by the governor—the second part of this stroke is approximately an adiabatic expansion; fourth stroke exhausts the gases.

It will be seen that the leading feature of this engine is (as Herr Diesel describes it) that of compressing the air to incandescence. No such temperature, however, really appears. The temperature reached at the end of the compression is lower than that developed later towards the end of the period of combustion, and this latter is only what occurs inevitably in explosion oil and gas engines worked under similar conditions. The temperature after purely adiabatic compression would according to theoretic calculation be about 1,000deg. F., but as the cylinder lining is thoroughly water jacketed, and, therefore, considerable cooling takes place during the compression, the actual temperature must be a good deal below this level.

There are four leading features of the Diesel engine that distinguish it from all other oil and gas engines: (1) The attainment of the temperature necessary for ignition by mechanical compression alone, so that all injected flame, or incandescent tube, or electric spark, or any other extraneous igniting devices are abolished. (2) The injection of the fuel takes place only after compression has been completed, and only during the first part of the working stroke; the compression in the working cylinder being that of air alone, therefore no explosive mixture exists in the cylinder before the beginning of the working stroke, and no premature ignition is ever possible. (3) The third feature is that the fuel is injected gradually into the highly-heated air, each drop of the spray burning immediately and quietly, so that no explosion takes place, while the period of injection and the quantity injected are delicately regulated by the governor in accordance with the demand for power. (4) The fourth feature is that the governing is effected within the four-stroke cycle period of thermodynamic action, and every such period has its working stroke. Most, if not all, other gas and oil engines are governed by the total cut out of the fuel injections during one or several such periods. Thus, with equal flywheel power the running is much steadier, and its speed uniformity coefficient is such as makes it very suitable for direct coupling to electric light dynamos.

Advantages.—(1) Being an internal-combustion engine, and not an explosion engine, it can at any time, without previous heating, be started from rest, and after a few revolutions take up the full load without further trouble. The operation is as follows: The engine is started by compressed air stored in what is known as the starting reservoir under a pressure of 800lb. upon the square inch, the said reservoir being charged by the air-pump during the previous run of the engine. (In the case of a new engine the makers send out these reservoirs ready charged. There is little or no danger of these vessels losing a charge; they have been known to stand from eight weeks to four months before the engine was started from them.) Assuming the engine to be left standing from the previous day's run, then with oil tanks charged and lubricators in order the engine is set just past the top dead centre. The screw-down valves on blast and starting reservoirs are opened. The engine now starts off as an air-driven engine. After five or six revolutions under these conditions the lever is thrown back. The engine will then start on its normal cycle as an oil-engine. The starting of the engine is very simple and quite certain, whether it has been stopped for a few minutes or for days, or, as before stated, even for weeks. (2) There is absolutely no smell, and the exhaust is free from unburnt gases; indeed, the gases are perfectly colourless and invisible when the engine is loaded, and upon test was found not to brown or discolour a sheet of pure white paper held close over the end of exhaust pipe for three minutes. When the engine is running without load, light wreaths of visible vapour come from the exhaust. (3) The combustion being complete, there is no carbon deposit to interfere with the working of valves or piston. After numerous examinations and prolonged running, the inside of cylinder, valve faces, and seats have been found perfectly clean and free from deposit, this deposit being one of the weak spots in all other gas or oil engines. (4) Small floor space being of the inverted marine type. (5) The ignition taking place inside the cylinder, and there being no external flame, hot tube, or electric spark, reduces the risks from fire to a minimum, and from an insurance point of view it is the safest engine imaginable.—E. FIELD.

Answer to No. 634 (*awarded* 5*s.*).—A fairly average estimate of the way in which the heat delivered to any ordinary internal-combustion engine is used is as follows: Heat converted into work, 20 per cent.; heat lost by radiation and conduction, 40 per cent.; heat lost in exhaust gases, 40 per cent. This gives a thermal efficiency of only 20 per cent. The theoretical maximum with a Carnot cycle is slightly over 72 per cent. Diesel set himself the task of devising means whereby the practical efficiency of 20 per cent. might be brought much nearer the theoretical efficiency of 70 per cent. The system of working common

Digitized by Google

to most internal-combustion engines—viz. (1) turning the fuel into gas, (2) mixing the gas with air, (3) compressing the mixture to about 80lb. pressure per square inch, and then igniting it by means of an extraneous igniting device—he condemned as being radically wrong. After making numerous experiments in order to discover the most economical method of utilising the fuel in an internal-combustion engine, Diesel came to the conclusion that he could not do better than to use the fuel in conjunction with air. He then laid down the following conditions for the most efficient working of an internal-combustion engine: (1) The temperature of combustion must not be produced by and during combustion, but independently of it and before its commencement, by the compression of pure air. (2) The combustible must be introduced gradually into the air thus brought up to the temperature of combustion by compression in such a manner that as heat is produced it is entirely absorbed by expansion of the gases, so that no internal work (as a rise of temperature would indicate) is produced, but only external mechanical work. If this condition were realised in practice, there would be no radiation losses, and no cooling jacket would be required. (3) A considerable surplus of air should be present beyond that theoretically required for complete combustion.

The Diesel engine works on a four-stroke cycle, which takes place as follows: (1) Fresh air is drawn into the cylinder during the outward stroke of the piston. (2) The air is compressed during the inward stroke to a high pressure, and consequently to a high temperature. (3) Fuel is admitted to the cylinder during the first part of the next outward stroke, combustion taking place as the fuel comes into contact with the highly-heated air. After the supply of fuel is cut off, the piston continues the rest of the outward stroke under the expansion of the gases, as usual. (4) The piston then returns, expelling the contents of the cylinder: this completes the cycle.

The advantages of the Diesel engine over a good make of ordinary oil or gas engine are as follows: (1) A thermal efficiency of nearly 40 per cent. has been obtained—this renders the engine very much more economical than the ordinary internal-combustion engine. (2) The attainment of the temperature necessary for ignition by mechanical compression alone, so that all extraneous igniting devices are abolished. (3) The injection of the fuel only after compression has been completed, and only during the first part of the working stroke; the compression in the cylinder being that of air alone, no explosive mixture exists in the cylinder before the beginning of the working stroke—premature ignition is thus impossible. (4) The fuel is injected gradually into the highly-heated air, each drop of the spray burning immediately and quietly, so that no explosion takes place, while the period of injection and the quantity injected are delicately regulated by the governor in accordance with the demand for power. It will thus be noticed that the governing is effected within the cycle, and every cycle has its working stroke. A large number of gas and oil engines are governed by the complete cutting out of the impulse from one or more cycles; the Diesel engine gives much steadier running with the same flywheel power than engines governed on the hit-or-miss principle. The engine is thus very suitable for connecting directly to dynamos. (5) The consumption of fuel per indicated horse-power is less at partial than at full loads, due mostly to the increased ratio of expansion. (6) The quantity of cylinder oil required by the Diesel engine is considerably less than that required by the ordinary gas or oil engine. The Diesel engine can also be adapted to work with coal dust or gas.—W. T. W.

PROVISIONAL ORDERS.

The additional following notices of intended application for provisional orders appear in the *Gazette*:

ELECTRIC LIGHT AND POWER.

Tamworth Corporation, electric light; Manchester Corporation, general powers (including electrical sub-station); Hampton-in-Arden Gas Company, electric powers; Skipton Urban District Council, supply of electric fittings; North Staffordshire Railway Company, electric power; Epsom (Surrey), Electrical Power Distribution Company, electric lighting; Acton, Metropolitan Electric Supply Company, lighting; Sutton-in-Ashfield Urban District Council, electric light; Brentwood Urban District Council, electric lighting; Ashford (Kent) and District Electric Supply Company, lighting; Milford-on-Sea Electric Supply Company, lighting; Devizes Urban District Council, electric lighting; Tavistock and District Electric Supply Company, lighting; Swindon Corporation, electric power; Derbyshire and Nottingham Electric Power Company; Chippenham Corporation, electric lighting; Doncaster Corporation, electricity supply extension; Widnes Corporation, electric light; Heysham Urban District Council, electric light; Stroud, Nailsworth, and Duraley (Gloucestershire Electric Power Company), lighting; Clevedon, Portishead, and Long Ashton (Western Electric Distributing Corporation, Limited), lighting; Ramsgate District Electric Supply Company, lighting; Bath Rural District Council, electric lighting; Walton-upon-Thames Urban Electric Supply Company, lighting; East London and Lower Thames Electric Power Company; Wanstead (Empire Electric Light and Power Company), lighting; Kirby-in-Ashfield Urban District Council, electric lighting; Kettering Urban District Council, electric power and light; Hampton Wick (Twickenham and Teddington Electric Supply Company), lighting; Sunderland (Durham Electrical Power Distribution Company, Limited), lighting; Newton Abbot (Urban Electric Supply Company), lighting extensions; Melksham Urban District Council, electric lighting; Maldens, Coombe, and Ham (Twickenham and Teddington Electric Supply Company), lighting: Bristol Corporation, electric lighting; North Worcestershire Electric Power Company, lighting; Brentford (Empire Electric Light and Power Company, lighting; Brynmawr Urban District Council, electric lighting; Southgate Urban District Council, electric lighting; Trowbridge (Western Electric Distributing Corporation), lighting and power; Mid-Shropshire (Worcestershire Electric Power Company), lighting and power, Acton (Empire Electric Light and Power Company), electric lighting and power; Brighton Corporation; Dewsbury Corporation; Dundee and Broughty Ferry and District; Folkestone Corporation; Glasgow Corporation; Leith Corporation; Liverpool Corporation (extensions); Ossett Corporation; Plymouth Corporation; Rochdale Corporation; Abercarn; Andover; Barhead; Beddington, Coulsdon, and Sanderstead; Bothwell District; Caerphilly Urban District Council; Cannock and District; Crediton; Dunfermline; Eastleigh and Bishopstoke; Eastwood and Cathcart; Glastonbury Corporation; Hanwell; Houghton-le-Spring and District; Johnstone; Kilpatrick; Kingswood; Lanark; Lothians; Maidenhead (extension); The Maldens and Coombe and Ham; Musselburgh; Penzance; Portpatrick; Renfrew; Rutherglen; Shettlestone; Sunderland Districts; Bradford-on-Avon Urban and Bradford-on-Avon Rural; Vale of Leven; Walton-le-Dale.

TRAMWAYS.

Aldershot and Farnborough Light Railway Commissioners: Newcastle-on-Tyne Corporation; Watford and District Tramways Company; Leeds Corporation; Isle of Thanet Light Railway Company; East Ham Urban District Council; Barrow-in-Furness Corporation; Stretford Urban District Council; Bristol Tramways Company, extensions; North and South Woolwich Electric Railway Company; Penarth Tramways Company; Soothill Nether Urban District Council; Llanelly Urban District Council; Bishop Auckland, Shildon, and Spennymoor (United Tramways, Light Railways, and Electrical Syndicate, Limited); Calverley Urban District Council; London, Camberwell, and Dulwich Tramways Company; Southport and Lytham Tramroad Company; London County Council; Ilford Urban District Council; Radcliffe Urban District Council; Tyneside Tramways and Tramroads Company; Dewsbury Corporation; Coulsdon (Croydon Rural District Council); Preston and Blackburn Tramways Company; Preston, Chorley, and Horwich Tramways Company; Manchester Corporation; Romford (Empire Electric Light and Power Company); Hope and Castleton Light Railway Commissioners; Liverpool Corporation; Morley and District Light Railway Commissioners; Sunderland Corporation; Middlesbrough, Stockton-on-Tees, and Thornaby (Imperial Tramways Company); Chesterfield Corporation; Belfast Corporation; Harrogate Waterworks Tramroads; Holywood; Mid-Cheshire; Preston and Lytham; Torquay; West Riding.

The total provisional orders of all kinds applied for is 272, as compared with 294 deposits for the session of 1903.

NEW COMMITTEES.

BEDFORD.—*Electricity*—Revised list: Alderman Kilpin, chairman; Councillor Talbot, vice-chairman; the Mayor (Alderman E. L. Moulton); Aldermen Carruthers and Walker; Councillors Black, Carter, Howard, Hockliffe, Jarvis, and Halliley.

CARDIFF.—*Electrical and Lighting*—Mr. P. Carey, chairman; Mr. Alfred Good, vice-chairman.

CROYDON.—*Lighting and Electricity*—Alderman Miller, chairman; Councillor Rogers, vice-chairman.

GRAVESEND.—*Electricity*—Councillor Enfield, chairman.

ISLINGTON.—*Lighting*—Alderman Mills, chairman; Alderman Walkley, vice-chairman.

MAIDSTONE.—*Light Railways*—The Mayor; Deputy Mayor; Aldermen McVitie and Brownscombe; Councillors Vaughan, Baker, Britt, Elmore, Tomlin, Wallond, Manning, and Styles.

Agency.—Messrs. Plutte, Scheele, and Co., 18 and 19, Queenhithe, E.C., have been appointed agents for the United Kingdom for Messrs. Schmahl and Schulz, of Barmen, manufacturers of electric light accessories.

Digitized by Google

LONDON TRAFFIC ENQUIRY.

On the 26th ult. the Royal Commission on London Locomotion held a further sitting, when **Mr. J. H. Brown,** representing the Battersea Borough Council, gave evidence as to the views expressed at a conference of borough councils Witness referred to the congestion at present existing at Clapham Junction, and suggested the extension of the South London Electric Railway from Clapham to the neighbourhood of Battersea Rise. His Council was strongly in favour of the appointment of a traffic tribunal by the Government which would bring into line the various schemes of communication of all kinds.

By the Chairman: His Council would willingly surrender their tramway veto to the tribunal, but they objected to surrender it to the London County Council. He felt that the County Council should be the tramway authority of London, rather than private companies. He did not know how they could induce the South London Electric Railway to extend their undertaking. He could not say whether they ought to be subsidised.

Sir George Trout Bartley: Would not the South London Electric Railway extend their line if it was thought to be profitable?—If it would pay a good dividend.

Why is it not done?—I do not know.

By the Chairman: He would allow the tribunal to hear proposals from private promoters, and allow them to approve of schemes.

Mr. H. G. Hills, town clerk of Wandsworth, gave evidence of a somewhat similar character. He suggested the extension of the tube railway from Clapham to Tooting and to Streatham Common. He also thought that a transit system should be formed on the loop line between the London and South-Western Railway and the London, Brighton, and South Coast Railway, and that a quick and frequent service of trains should be run from Waterloo *viâ* Clapham Junction, Wandsworth, East Putney, Southfields, Wimbledon, Merton, Tooting Junction, Streatham, Tulse-hill, Ludgate-hill, or London Bridge, or branching off from Tooting Junction to Balham, Wandsworth Common, Clapham Junction, and Victoria.

On the following day **Mr. J. H. Robinson** gave evidence on behalf of the Stepney Borough Council. With regard to the view expressed by Mr. G. L. Gomme, on behalf of the London County Council, that the supervision of the breaking up of streets by private companies should be transferred from the borough councils to a central authority, witness said that presumably the central authority was intended to be the London County Council. The Stepney Borough Council strongly opposed that suggestion, on the ground that the borough councils had in the past discharged their duties with efficiency.

Mr. James Rush Dixon, the surveyor to the metropolitan borough of Shoreditch, said that in the opinion of his Council it would relieve congestion if passenger subways were provided under such places as the intersection of Old-street and Kingsland-road, Shoreditch High-street and Great Eastern-street and Commercial-street. Owing to the exceptionally heavy debt of Shoreditch and the recent immense increase of rates, some new source of income would have to be found if the necessary street improvements were to be undertaken.

Mr. F. S. Robinson, town clerk of the metropolitan borough of Greenwich, gave similar evidence, and the Commission adjourned.

LEGAL INTELLIGENCE.

THE SPEED OF ELECTRIC TRAMCARS.

At the South-Western Police Court on Tuesday morning, Mr. Moffat Ford attended before Mr. Garrett in the matter of the 10 summonses he had issued against the drivers of the London County Council electric tramcars for exceeding the legal speed limit.

Mr. Ford stated that the Highways Committee of the County Council had now reported upon the Motorcar Act of 1903, and in their report the committee professed entire agreement with the Local Government Board that "the expedients provided by the Act for the reduction of the speed limit of motorcars to 10 miles an hour should not be resorted to." He (Mr. Ford) had been led to believe that his efforts in showing the absurdity of the 10-miles-an-hour speed limit had not been entirely without effect in the decision the committee had arrived at. The full committee of the Council were meeting that afternoon, and he should not like them to be under the impression that, in spite of the recommendations of the committee, the summonses were inevitably to be heard on Thursday next. Under the circumstances he did not feel justified in carrying the matter to any further extreme than necessary, and he suggested that, pending the final decision of the full Council, the summonses might be adjourned *sine die*. A representative of the Council was in attendance, and he understood that this gentleman was prepared to agree to the course he suggested.

The **Magistrate,** in reply, said that he considered Mr. Ford's suggestion a very proper one.

The summonses were accordingly adjourned *sine die*.

IN BANKRUPTCY.

In the matter of William Henry Hooley and John William Talbot, carrying on business, in co-partnership, under the style of Hooley, Talbot, and Co., at Regent-street, Rugby, as electrical engineers and contractors, the official receiver (Mr. E. T. Peirson) has issued a summary of the debtors' statement of affairs. This shows gross liabilities of £339. 13s., of which £271. 8s. 4d. is expected to rank. The assets, after deducting preferential creditors' claims, are estimated to produce £106. 15s. 4d., leaving a deficiency of £164. 13s. In the separate estate of William Henry Hooley the deficiency is put down at £2. 16s., and in that of John William Talbot of £1. 1s. 11d. Debtors give as the cause of failure "insufficient capital, delay of the urban district council in supplying electric light, and loss upon a contract owing to the action of one of our customers."

COMPANIES' MEETINGS AND REPORTS.

ARON ELECTRICITY METER.

In their report for the year ending Sept. 30, 1903, the directors state that the profit and loss account for the year, after providing for depreciation and the share of expenses and discount on the issue of debentures, show a net profit of £2,125 18s. 8d., which has been carried to the debenture sinking fund in accordance with the provisions of the trust deed. The directors are pleased to record a considerable change for the better in the affairs of the Company, which may be ascribed to the following causes: the apparent revival of the electrical industry on the Continent has created a proportionately larger demand for Aron meters, especially in Germany; the completion of the factory at Schweidnitz has enabled the Company to manufacture both cheaper and more advantageously; the manifest advantages of the Aron meter have created a reaction in its favour, which is distinctly noticeable in quarters where other instruments were afforded encouragement in recent years. The increased sales during the last year led your directors to expect better results than have actually been attained; the economies effected in the manufacture have, however, so far not been sufficiently large to compensate for the required reduction in the selling prices. The directors have persevered in their efforts to stimulate business in England, and the expenditure incurred thereby has materially reduced the profits for the year. Prof. Aron has successfully completed his experiments in connection with the production of a new and cheap meter for alternating currents, which will shortly be placed on the market. Two of the directors, Messrs. S. Barclay Heward and Mr. R. W. Wallace, K.C., retire from office by rotation this year, but being eligible, offer themselves for re-election.

NEW COMPANIES REGISTERED.

Kingswood Electric Supply Company, Limited.—Capital, £1,000. Object: to adopt an agreement with the Bristol Trust, Limited, to carry on the business of suppliers of electric light, heat, motive power, or otherwise, electrical engineers, etc. Registered office: 46, Newman-street, Oxford-street, London.

Archibald J. Wright, Limited.—Capital, £3,000. Object: to acquire and carry on the business of A. J. Wright, 318, Upper-street, Islington, of electrical and mechanical engineers, dealers in electric, magnetic, telegraphic, telephonic, other appliances, cycle and motorcar manufacturers, etc.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Maidstone.—The Corporation invite tenders for the construction and equipment of light railways. Tenders by Dec. 7.

Preston.—The Corporation invite tenders for a traction switchboard and accessories. Tenders by Dec. 12. See advertisement in last issue.

London, N.—The Hornsey Borough Council invite tenders for the supply of 100 cast-iron lamp columns. Specifications from the Surveyor. Tenders by 14th inst.

Pontypridd.—The Urban District Council invite tenders for free wiring, and for Section O, the supply of tramcars. Tenders by 24th inst. See advertisement.

Stockton-on-Tees.—The Corporation invite offers for hiring or hire-purchase system for motors to be fixed on their mains. Tenders by 15th inst. See advertisement.

Govan.—The Corporation invite tenders for the supply, delivery, and erection of coal bunkers, conveyor, and electric capstan. Tenders by 28th inst. See advertisement.

Birmingham.—The Birmingham Tame and Rea District Drainage Board, 9, Bennett's-hill, Birmingham, invite tenders for three steel Lancashire boilers. Tenders by Dec. 8.

Greenwich.—The London County Council invite tenders for the supply, delivery, and erection of four 3,000-kw. generators with exciters. Tenders by 10 a.m. on Dec. 8.

York.—The North-Eastern Railway Company invite tenders for telegraph apparatus, telegraph wire, and line stores. Forms of tender from Mr. C. H. Ellison, superintendent, York. Tenders by Dec. 7.

Greenwich.—The London County Council invite tenders for six electrically-driven three-throw boiler feed pumps. Specifications, etc., at the County Hall, Spring-gardens, S.W. Tenders by Jan. 19.

Stockport.—The Corporation invite tenders for supply and laying of about 1¾ miles of distributing cable. Specifications from Mr. A. J. H. Carter, Electricity Works, Stockport. Tenders by 10th inst.

Cape Town (South Africa).—The Directors of the Cape Town Industrial Exhibition (International) invite offers for lighting the

Digitized by Google

grounds, etc. Tenders to Palmerston House, Old Broad-street, London, E.C.

Sydney (N.S.W.).—Tenders are asked for the supply of continuous and alternating current meters. Specifications, conditions, and forms of tender are obtainable from Messrs. Preece and Cardew, 8, Queen Anne's-gate, S.W.

London, W.—The Great Western Railway Company invite tenders for the supply, delivery, and erection of water-tube boilers, engines, three-phase generators, and auxiliary plant at Park Royal, near Acton. Tenders by Dec. 7.

North-Eastern Railway.—The Directors invite tenders for arc lamp carbons and electric wires and cables, etc., for the first half of 1904. Specifications, etc., from Mr. E. H. Clark, Stores, Gateshead. Tenders by Dec. 7.

Warrington.—The Electricity Committee invite tenders for the supply of earthenware ducts for the drawing-in system of mains. Specifications from the Electrical Engineer, Howley, Warrington. Tenders by 14th inst.

Glasgow.—The Corporation invite tenders for (1) 2in., 4in., and 6in. cast-iron pipes, with trough ends for cables; and (2) cast-iron fuse-boxes. Specification from Mr. W. A. Chamen, 75, Waterloo-street, Glasgow. Tenders by 7th inst.

King's Norton (Birmingham).—The Urban District Council invite tenders for about two miles of electric cable for tramways, including laying. Specifications from Mr. C. H. Gadsby, 20, Victoria-street, Westminster, S.W. Tenders by 10th inst.

London County Council Tramways.—The Council invite tenders for the wiring and fitting for electric lighting of five sub-stations and three car-sheds in connection with the tramways. Tenders by Dec. 5. See advertisement in former issue.

Brighton.—The Council invite tenders for six water-tube boilers; a system of steam, exhaust, feed, blow-off, and suction pipes; and cast-iron storage tanks. Specifications, etc., may be obtained from Mr. Francis J. Tillstone, Town Hall, Brighton. Tenders by Dec. 7.

Christchurch (New Zealand).—Tenders are invited for the complete installation of electrical tramways, other than buildings. Specifications, etc., may be obtained from the Agent-General for New Zealand, Victoria-street, S.W. Tenders by March 17. See advertisement.

Manchester.—The Electricity Committee invite tenders for the supply, delivery, and erection at the Stuart-street station of cast-iron plates for tops of flues, dampers, and opening apparatus. Specifications from the Secretary, Electricity Department, Town Hall. Tenders by 11th inst.

Belfast.—The Committee invite tenders for the supply and erection of a complete heating and ventilating system, including steam boilers, heaters, etc., engines, blowers, and electric fans. Tenders by Dec. 4 to Messrs. Young and Mackenzie, architects, Scottish Amicable Buildings, Belfast.

Culiacan (Mexico).—Tenders are invited for lighting the town by electricity: 60 arc lamps of 1,200 c.p. and 110 incandescents of 50, 30, and 16 c.p. will be required. Propositions will be received by letter until Dec. 31 in the Secretaria del Ayuntamiento, Culiacan, where further information may be obtained.

West Ham.—The Education Committee invite tenders for the electric wiring and fittings and for the hot-water heating apparatus required at the Whalebone-lane Higher Elementary School, Stratford, E., and Shipman-road School, Custom House, E., now in course of erection. Tenders by Dec. 14. See advertisement in former issue.

London, S.W.—The London County Council invite tenders for the supply and delivery of about 6,850 tons of steel girder tramway rails, fishplates, and bolts and nuts, and for 4,100 tons of steel slot rails, and 1,490 tons of steel conductor tee rails required for electric traction on the Council's tramways. Specifications, etc., from Engineers' Department, and tenders to the Clerk, County Hall, Spring-gardens, by Dec. 15.

Sydney (New South Wales).—Tenders will be received at the office of the Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 30, for the supply and delivery at the departmental stores, Sydney, of telegraph, telephone, and electric light material. Specifications, etc., may be seen and tender forms obtained at the General Post Offices, Sydney, Melbourne, Brisbane, Adelaide, Hobart, and Perth.

Italian Arsenals.—Tenders are invited for the supply of electric lamps for the lighting of Italian warships, and will be received simultaneously at the Directorates-General of Royal Arsenals at Spezia, Naples, and Venice, at 11 a.m. on Dec. 1. The electric lamps to a total value of 40,000 lire (about £1,600) are to be delivered at the Royal Arsenals at Spezia, Naples, Venice, and Taranto. Particulars may be obtained from the Admiralty, Rome.

RESULTS OF TENDERS.

Paisley.—Messrs. Bruce Peebles and Co., Limited, Edinburgh, have obtained the tender for a 1,600-kw. traction and lighting generator for the Corporation.

Newport (Mon.).—The Borough Council have accepted the tender of Messrs. Johnson and Phillips, who were the lowest of 36 tenderers, for three 50-h.p. motors, etc.

Oldham.—The tender of H. A. Jackson and Co., Standish-street, Burnley, has been accepted for arc and incandescent lighting and power circuits in Greenhill station.

Croydon.—A tender has been accepted of Mirrlees, Watson, and Co., Limited, for condenser, air-pumps, etc., for a capacity of 36,000lb. of steam per hour, piping, and Koppel cooling tower, at £2,709.

Johannesburg.—Messrs. A. W. Penrose and Co., 109, Farringdon-road, E.C., have secured the entire order for generating plant, including engine, dynamos, etc., and also that for the two passenger and one goods lifts, for the new building of Messrs. Harvey, Greenacre, and Co., of Johannesburg.

Coventry.—The Electric Lighting Committee have accepted the following tenders: for the construction of turbine and condenser foundations, E. Morley, £834; and for turbine steam-piping, George Fletcher and Co., £167.

Sunderland and District Tramways.—Messrs. Bruce Peebles and Co. have obtained the contract for the complete equipment of 1,000-h.p. power-house, complete overhead equipment for 19 miles of track, and 60 complete electric equipments for double-deck tramcars, including cars, for the Sunderland and District Tramways. The contract amounts to about £81,000.

Gravesend.—The British Westinghouse Company have secured the contract for the supply of a 100-kw. steam dynamo for the Gravesend Corporation. The set will consist of a Westinghouse generator driven by a Belliss and Morcom steam-engine of standard pattern, running at 475 revolutions per minute. It will be shunt-compound wound, and will give 460 to 550 volts, according to the arrangement of the windings.

Dartford.—The Metropolitan Asylums Board have received the following tenders for installing a complete system of telephones at the Darenth Asylum, Dartford, Kent:

P. Dewhurst, 24, Birley-street, Blackpool (accepted)	£245 10 0
E. T. Mackrill and Sons, Aylesbury, Bucks	247 13 7
F. Hodgson and Co., 24, Queen Victoria-street, E.C.	257 18 0
Cox-Walkers, Darlington	263 0 0
Private Wire and Telephone Installation Company, Limited, 5, Palmer-street, Westminster, S.W.	284 17 0
W. Defries, 146-7, Houndsditch, E.C.	289 0 0
New System Private Telephone Company, Limited, 36, King William-street, E.C.	298 18 10
Western Electric Company, 171, Queen Victoria-street, E.C.	319 4 0
Wippell Bros. and Row, 243-4, High-street, Exeter	340 0 0
G. Weston and Sons, 153, Fenchurch-street, E.C.	344 0 0
J. Sax and Co., Limited, 51, Rupert-street, W.	345 0 0
Ward Bros., Bevois House, 28A, Basinghall-street, E.C.	345 12 9
H. G. Rider and Co., 27, Chancery lane, W.C.	349 0 0
British Home and Office Telephone Company, 49, Finsbury-pavement, E.C.	364 0 0
W. H. Saunders and Co., 1, Palmer-street, Westminster, S.W.	369 0 0
Comyn Ching and Co., Limited, 54, 56, 58, Castle-street, Long-acre, W.C.	374 0 0
B. and R. Durant, Chapeltown, Sheffield	413 13 5
Fuller, Macleod, and Co., Limited, 9, Red Lion-court, Cannon-street, E.C.	420 0 0
Jackson Bros., The Broadway, Plaistow	440 0 0
Donnison, Sillem, and Co., 116, Great Portland-street, W.	450 0 0
A. Smith, 54 Hounds-gate, Nottingham	566 0 0
National Telephone Company, Limited, Salisbury House, London-wall, E.C.	620 0 0
F. J. Coleby and Co., 7, Thayer-street, Manchester-square, W.	750 0 0

Bermondsey.—The Council have received the following tenders for Contracts Nos. 14, 15, and 16. Contract 14 is for the feeder cables required in connection with the extension of the supply system; Contract 15 for the extension of arc lighting; and Contract 16 for that portion of the cable work involved in supplying and laying cables through the Surrey and Lavender Dock locks:

Contract 14.

Western Electric Company	£4,967 10 0
Johnson and Phillips	5,071 14 10
Siemens Bros.	5,278 18 0
Callender's Cable Company	5,371 8 4
Alternative, £5,280. 0s. 2d., lead less than specified.	
British Insulated and Helsby Cables, Limited (accepted)	5,285 4 2
Messrs. Glovers	5,331 16 6
St. Helens Cable Company	5,542 10 3
Alternative, £5,393. 1s. 8d., not to specification.	
Land und Seekabelwerke Aktiengesellschaft	5,732 13 7

Contract No. 16.—(Section A) Cables.

British Insulated and Helsby Cables (accepted)	463 10 10

London.—The City of London Electric Lighting Company has recently placed with the British Westinghouse Electric and Manufacturing Company an order for another 1,800-kw. direct-current,

Digitized by Google

shunt-wound generator, to be mounted direct on the shaft of the driving engine. This machine will run at 75 revolutions per minute, and will be practically a duplicate of several other 1,800-kw. machines which the British Westinghouse Company has supplied to the same station.

BUSINESS NOTES.

TRACTION.

Leicester.—Major Pringle, R.E., one of the inspectors of the Board of Trade, has made an official inspection of the permanent way of the completed tramway.

Battersea.—The Borough Council have approved the London County Council's scheme for tramways from Clapham Common to East-hill, Wandsworth.

Blackpool.—A new traction generating set will shortly be required for the electricity works in order to supply the Lytham and St. Annes Tramway with energy.

Snowdon.—Notice of an intended application to the Light Railway Commissioners for an order has been given in the case of the proposed Snowdon and Bettws-y-coed Light Railway.

Durham.—The British Electric Traction Company have informed the Town Council that they intend shortly to begin the construction of the authorised tramway from Durham to Brandon.

Electric Railway for Woolwich.—The *London Gazette* contains notice of a Bill seeking power to construct an electric (underground) railway between North Woolwich and South Woolwich.

Brighton.—A public meeting was held this week, when a resolution was carried condemning the action of a minority in obstructing on the Town Council the extension of the tram system to Preston.

Dewsbury.—It is stated that the Corporation are considering the question of purchasing the tramways within the borough. Notice of intention to do this must be given before the end of the year.

Rowley Regis.—At a meeting of the District Council on Monday it was reported that special efforts are being made to secure improved tramway facilities on the Halesowen and Oldbury main roads.

Wigan.—The question of tramway extension from Wigan to Standish has been pending for a considerable time, and there is reason to believe that before long a satisfactory result will be arrived at in the matter.

Liverpool.—The Tramways Committee have decided that the proposed Lodge-lane and Aigburth tramway is not wanted, but it was stated at Wednesday's meeting of the City Council that the matter was entirely in the Council's hands.

Municipal Motors at East Ham.—It is proposed to run municipal motor omnibuses in East Ham. The Tramways Committee of the Urban District Council report being about to visit Hastings to inspect the double-decked vehicles plying there.

Flintshire.—The promoters of the Flintshire tramways scheme have resolved not to seek powers from Parliament next session, but to defer their application till 1905, so as to have the benefit of a more strongly organised and concentrated local support.

District Railway.—It is stated that, owing to a subsidence on the electric section of the District Railway between Park Royal and Alperton, single-line working has been resorted to, the service on the section consisting for the present of one train an hour.

Wandsworth.—The question of the construction of new tramways at Streatham is still under consideration by the Borough Council, who cannot make up their minds to make a contribution towards the cost of the street widenings in spite of popular sympathy with the scheme.

Lambeth.—The Borough Council are going to send a deputation to the County Council to see if the latter will accept £20,000 in respect of street widenings for the tramways instead of £40,000, which is the one-third share of the estimated cost required by the County Council.

Belfast.—The City Council, at their meeting on Tuesday, approved the draft Tramways Bill to be promoted in the next parliamentary session. It was agreed to insert a proviso that the leasing power shall not be exercised without a *plébiscite* of the electors being taken on the question.

Electric Tramways for Minerals.—An electric tramway for the carriage of minerals has been opened from East Pool and Agar United Mines to Tolvaddon stamps. The line has been put down by the Urban Electric Supply Company, Limited, under contract with the mine company.

Swansea.—A movement is on foot amongst Oxford-street and Temple street tradesmen with the object of seeing if the Corporation cannot be induced to abandon the scheme for running the new tramway system through those streets. Major Druitt, of the Board of Trade, has made an enquiry into the objection.

Provincial Tramways Co.—The accounts of the company for the year ended Sept. 30, after setting aside £6,000 for depreciation at Plymouth and Grimsby, admit of the payment of a dividend on the ordinary shares of 3s. per share, making 6s. per share, or 3 per cent. for the year. The balance carried forward will be about £2,700.

Bradford.—A trial trip was run on Monday over the new tramway which has been laid in Church Bank, which provides the steepest gradient on the Bradford tramways—viz., 1 in 9. Mr. C. J. Spencer, the general manager, drove the trial car, and the run was satisfactorily accomplished, the car being pulled up whilst travelling at a fair speed in half its own length.

Poplar.—The General Purposes Committee reported to the Borough Council on Wednesday that, being of opinion that the north and south of London should be better connected, they had approved the proposals of the London County Council to seek powers to construct tramways from East India-road, through the Blackwall Tunnel, to Greenwich.

Glasgow.—The Corporation have agreed to fit covers to the upper decks of one or two cars by way of experiment. The Kirkintilloch Town Council intend to send a deputation to the City Tramways Committee urging an extension of the lines to that town. The extension from Partick to Cambuslang was opened for traffic on Wednesday. The distance is 8½ miles.

Beckenham.—At the last meeting of the Town Council, the question of the system of traction to be adopted on the proposed tramways was debated at length. The committee advocated the overhead trolley, but eventually it was decided to entertain the conduit system as an alternative system, and it was agreed to communicate with the British Electric Traction Company in the matter.

Devonport.—A sub-committee of the Corporation Tramways Committee has received a report from the borough surveyor as to the probable cost of certain road widenings and improvements required by the Devon County Council as a condition to their consent to the proposal to construct a light railway from the borough boundary to Crownhill. The report was afterwards accepted by the Tramways Committee.

Wakefield.—The Leeds Corporation Tramways Committee at their meeting on Monday received an application from the Wakefield and District Tramways Company for permission to run cars over the Leeds Corporation lines from Thwaite Gate into the centre of the city. It is the intention of the Corporation to establish connection with the Wakefield tramways in the manner suggested, but the matter was postponed for further consideration.

Withington.—The Council at their last meeting decided that, after considering the memorials and correspondence for and against the proposed tramway extension to Chorlton-cum-Hardy, the construction of a double line of tramways along the Wilbraham-road and Alexandra-road South to the boundary of Moss Side be carried out. A sub-committee was authorised to conclude the negotiations with the Manchester Corporation as to the terms of the lease.

Woolwich.—The consent of the Borough Council has been given to the proposed doubling by the London County Council of the existing tramway from Beresford-square to High-street, Plumstead, to the county boundary. Upon condition that the London County Council grant a loan for the purpose, a contribution is to be made by the Borough Council of one-third of the cost of the necessary street widening, such contribution not exceeding the sum of £4,800.

Paddington.—The Borough Council on Tuesday considered a letter from the London County Council asking for consent to a proposed tramway from the Marble Arch to Cricklewood and for a contribution of one-third of the cost of the necessary street widenings. The recommendation of the special committee was against the proposal, but an amendment that the Borough Council would consider the scheme provided that the County Council agreed to bear the entire cost of the street widenings was carried by a large majority.

Leith.—The Town Council have published notices of their intention to apply for a provisional order in next session of Parliament for power to acquire from the Edinburgh Street Tramways Company the existing tramways in Leith, to construct new tramways, and make agreements for promoting through traffic between the Leith lines and the Edinburgh lines. They ask power to acquire the existing tramways, and to have any agreement entered into, or that may be entered into by them, with the Edinburgh Street Tramway Company confirmed.

Aberdeen.—On Saturday morning Colonel P. G. von Donop made his official inspection of the Ferryhill and Torry sections of the Corporation tramways. The inspector expressed himself as perfectly satisfied with the manner in which the lines had been constructed, and commented favourably on the smoothness of the running. He was asked that on this section the maximum speed of 14 miles per hour should be allowed, but Colonel von Donop said that he never granted the maximum speed within a municipal boundary. He fixed the speed at 12 miles an hour.

Islington.—Having regard to the difficulty of dealing with certain bridges, the London County Council asked the Borough Council to consent to the adoption of the overhead trolley as against the conduit system in the electrification of portions of their northern tramways. The Works Committee of the local Council now report, however, that they are strongly in favour of the conduit system, and find that Finsbury, Hackney, Shoreditch, and Stoke Newington all agree with them that "the overhead trolley system is totally unsuited to the needs of London north of the Thames."

Seaham.—The District Council have passed a resolution to the effect that a committee be appointed for the purpose of considering and ascertaining what steps can advantageously be taken by the Council, either alone or by co-operation with any other public authority, company, or persons, with a view to bringing the Council's district into more convenient or direct communication with Seaham, Murton, Easington, and Horden Collieries and the surrounding districts, and more particularly as to the desirability of the construction of a coast road uniting Seaham Harbour to the collieries to the south and a light railway or tramway to Murton Colliery.

Edinburgh.—The directors of the Edinburgh and District Tramway Company have intimated to the Leith Corporation, with regard to the negotiations between them for the working of the Leith tramway system and the securing of through traffic between Edinburgh and Leith, that they cannot approve of the conduit-cable combination by which it was proposed Leith electric cars should be carried over a portion of Edinburgh cable lines, and that the only alternative solution of the difficulty was the carrying of the cable into Leith, to the foot of Leith-walk. This the Leith Town Council will not agree to, and negotiations have been broken off.

Digitized by Google

Derby.—The contractors have commenced the work of erecting the poles in connection with the new electric tramways on certain routes. The committee have decided to substitute wood paving for granite paving in St. Peter's-street, from East-street to the spot, in connection with the construction of the electric tramways, at an extra cost of £431. The extra cost of wood over granite paving for the whole of the remaining routes in the contract will be £38,682. The committee have visited the works of the Brush Electrical Engineering Company at Loughborough with respect to the new electric cars.

Paris Metropolitan.—A Paris message dated Nov. 30 states that another fire occurred on the Metropolitan Railway there in the morning. A workman's train, while travelling on the overhead section about six o'clock, suddenly burst into flames owing to a short-circuit. The train was at once brought to a standstill. Two cars were completely burnt out. The traffic was interrupted for some time. The accident happened not far from the scene of the recent catastrophe which involved such great loss of life. Shortly after traffic had been resumed another fire occurred near the station of the Boulevard Barbes. The motorcar of the train was burnt. There were no casualties.

Newcastle.—A special meeting of the Town Council is to be held on Tuesday to consider the proposed Bill for next session of Parliament, in which extensive tramway powers are sought. At Wednesday's meeting of the Council the Tramways Committee presented a report recommending that application be made to the Board of Trade for sanction to borrow £192,516 for tramway purposes. Up to the present the tramways have cost £1,061,632 for 40 miles of track and equipment, and the amount already sanctioned is £869,116. For tramway purposes under the Act of 1899 it was estimated that a further sum of £192,516 would be expended on the completion and equipment of the tramways. The report stood over for consideration.

Bristol Accident.—A coroner's jury on Wednesday investigated the circumstances of the fatal tramway accident at Bristol. The evidence showed that the driver lost control of the car while descending a steep hill from Clifton Downs, with the result that there was a collision with another car travelling in the same direction. A cyclist named Charles Healls was caught between the cars and died three days later from his injuries. The driver, who was seriously hurt, said that the brakes failed to work, though they were afterwards found to be in good order. The jury returned a verdict of accidental death, and attributed the collision to the driver's "error of judgment" in failing to put forward the "reverser" before starting the car.

Holborn-to-Strand Shallow Tramway.—Already some 395ft. of this tramway is completed—that from the Gaiety Theatre to Drury-lane, and work on the section to run under the Kingsway has been started. To facilitate this work it is proposed to shut up the western end of Great Queen-street; but this proposal has naturally provoked much indignation, and a meeting of residents and tradesmen of the street held on Tuesday night let it be plainly understood that any attempt to interfere with their business or convenience in the manner suggested would be strongly resisted. A sum of £36,000 has been spent on the section completed, and as this is below the estimate, the Works Department of the Council is congratulating itself on such a satisfactory result.

Additional Traffic Returns.—Anglo-Argentine, £2,122 increase; Barcelona Ensanche y Gracia, £111 increase; Barcelona, £48 decrease; Brisbane, £122 increase (month of November, £10,544, increase £253), British Columbia Electric (month of March), gross earnings £10,352, net income £2,659; Buenos Ayres and Belgrano Electric, £25 decrease (month of November, £14,142, increase £444); Calcutta, £260 increase; Cape Town (month of October), receipts £16,229, expenditure £9,044; Isle of Thanet Electric, £1 increase; Lisbon Electric (month of October), receipts 93,725 milreis, expenses 50,350 milreis; Mexico Electric (month of August), receipts £48 600, expenses £27,900; Perth Electric, £227 increase; Port Elizabeth (month of October), receipts £3,972, expenditure £2,879.

Cardiff.—At a meeting of the Tramways Committee on Monday the Town Clerk reported that he had received the sanction of the Board of Trade for the following work: the substitution of double and interlacing lines for single lines in Mill-lane; laying of junctions between Newport-road and Glossop-road; a junction between Penarth-road and Mill-lane; and a passing place in the Hayes. The Borough Engineer reported that the construction of the tramway between Corporation-road, Grangetown, and the Great Western Railway bridge would be completed this week. It was stated that the amount expended in the reconstruction of the tramway lines taken over from the Provincial Tramway Company was £70,577, and it was agreed to apply to the Board of Trade for sanction for borrowing that sum.

New South Wales.—The report of the Railway Commissioners (Mr. Charles Oliver, chief commissioner, and Mr. David Kirkcaldie and Mr. W. Fehon, commissioners) for the quarter ended Sept. 30 has been laid before the State Parliament. The tramways show increased earnings of £18,940, the receipts having risen from £166,900 to £185,840, the expenses at the same time coming up by £15,711. The tramways, comprising 125 miles of line, are largely worked on the electric system, and are very popular. During the quarter the number of passenger journeys was 32,000,000. The outlook generally in the State seems promising, the present season being the most favourable experienced for very many years, and a record harvest seems assured, with corresponding inflation of the railway receipts.

Mr. Yerkes's Scheme.—The New York correspondent of the *Daily Telegraph* has been enlightening its readers with regard to Mr. Yerkes's scheme of rapid transit for London. There is much in the telegrams which is old; little that is new. The correspondent, however, gives the names of the American directors of the syndicate, which include Messrs. James Hyde, of the Equitable Life Insurance Company, Richard McCurdy, of the Mutual Life Company, James Speyer, James Blair, J. Jefferson Coolidge, jun., and President L. F. Losee, of the Baltimore and Ohio Railroad. The particulars of the large power-house now under erection at Chelsea are by now ancient history, but the *Daily Telegraph* correspondent dishes them up in the nature of a revelation. His statement that the equipment of the lines is to be of American make is, we believe, far off the mark.

Kirkcaldy.—On Saturday an extension of the tramways to Whytecauseway was inaugurated. It will meet the wants of a large population, being in direct touch with Kirkcaldy railway station. The initial part of the scheme has been conducted with financial success, while no accidents of a serious kind have occurred, and a further extension of the undertaking is now in contemplation by the laying of a double line of rails from the cottage hospital to Dysart, for which notice of a Bill has been given for next session of Parliament. A special service of workmen's cars is to be instituted at the beginning of next week, and to meet the increased traffic seven new cars have been ordered (making 22 in all), while a new 500-h.p. engine and dynamo is to be erected at the generating station. The new route is lit throughout by arc lamps. The demand for electricity, both for power and lighting, is gradually on the increase.

Birmingham and Foreign Rails.—At a meeting of the Birmingham City Council on Tuesday, the question of foreign *v.* English rails was vigorously discussed. The resolution submitted by a private member was in the following terms: "That, in the opinion of this Council, it is much to be regretted that the Tramways Committee should have considered it necessary to purchase tramrails from abroad at a time when British industry needs encouragement and support." He contended that it was not necessary for the committee to go abroad for tramrails. Two reasons had been put forward in favour of the purchase. The first was on account of cheapness, and the second that the foreign rails were superior to the English-made articles. The former he agreed was correct, but he contested the latter. But even the price ought not to be a consideration to any large extent with a Corporation like that of Birmingham. The Sheffield Corporation purchased English rails rather than foreign, although they paid 10s. more than they would have to pay for foreign rails. He contended that if the rails were made according to the specifications of the Engineering Standards Committee, the English manufacturer would be able to compete successfully with his German rival. Engineers, he found, were agreed in favour of British rails, and declared it was a fallacy to suppose that English rails were inferior to German. He was informed, however, that Birmingham omitted some of the tests usually applied to those rails, and this was an advantage to the foreigner. The saving in connection with the German rails purchased would at the utmost not be more than 6s. per ton, and he thought under the circumstances the English firm, which was that amount higher, might have been asked to reconsider before the contract was signed. Mr. Lovesey, in seconding the motion, thought the ratepayers of the city would have been better pleased if their money had been spent in the home market rather than in encouraging foreign competitors. Mr. Alderman Beale, the chairman of the Tramways Committee, pointed out that the Corporation bought no rails on their own account until the summer of this year. Before that time the rails were bought solely on behalf of the companies that owned the lines. The committee did not want to buy foreign rails. It simply did so because it thought they were the cheapest and to the advantage of the tramway companies. No one regretted more than the members of the Tramways Committee that the goods of British manufacturers were not so low in price as the foreign material. The resolution was carried with two dissentients. A resolution was then moved, "That in asking for tenders for manufactured articles of any description if the same are made, or can be made, in Great Britain they shall be specified to be of British manufacture. This is to apply to all manufactured articles purchased without tender and to manufactured articles used in buildings, machinery, plant, stores, rolling-stock, etc., in every department of the Corporation." After discussion the matter was referred to the General Purposes Committee, with instructions to obtain information from the various committees as to the probable effect of the proposed resolution.

London County Council.—Chief among the tramway matters considered at the usual weekly meeting of the London County Council on Tuesday was the question of the system of traction to be adopted for the reconstruction for the electrical working of the first sections of the Council's lines in the North of London. These lines are known as follows: (*a*) Theobalds-road terminus, *via* Clerkenwell-road, Old-street Great Eastern-street, Commercial-street, and Leman street, to near the London Docks; (*b*) Norton Folgate terminus, *via* Shoreditch, Kingsland-road, High-street, and Stoke Newington-road, to Stamford Hill; (*c*) Aldgate terminus, *via* Commercial-road, Commercial-road East, and East India Dock-road, to Poplar; (*d*) Moorgate-street terminus, *via* Finsbury-pavement and City-road, to junction with Old-street; (*e*) Holborn terminus, *via* Gray's-inn-road, to junction to Theobalds-road; and (*f*) along Old-street and Great Eastern-street and Shoreditch. The length of these tramways is about 22¼ miles of single line, and it will be practicable for the whole of them to be worked from the electric generating station which is being established at Greenwich. In a report which the Highways Committee submitted to the Council in October they stated that it would not be possible for them for some time to come to present estimates of the cost of the work, as trial holes would have to be made at certain points along the routes in order to ascertain depth available for the laying of tramway conduits over railway and canal bridges, and the positions of pipes, wires, and other obstructions under the carriageway. These investigations are being proceeded with, but are not yet sufficiently advanced to permit of estimates being framed of the cost of the work. In view, however, of the fact that the Council will have to obtain the approval of the Board of Trade to the system proposed to be adopted for these lines, the committee think that the necessary plans should be at once forwarded to the Board, and to the several borough councils concerned, in order that the Council may be in a position to arrange for the carrying out of the work so soon as the estimates of the cost are ready. The lines specified form one-half of those which on July 7 the Council

Digitized by Google

decided should be constructed, or reconstructed, for an underground conduit system of electrical traction, and the committee propose that the system shall be exactly the same as that approved by the Council on Nov. 10 in connection with the construction of the tramways along St. John-street, St. John-street-road, and Rosebery-avenue. The following recommendations were accordingly adopted by the Council on Tuesday: (*a*) That the underground conduit system of electrical traction, approved by the Council on Nov. 10, 1903, for the construction of the new tramways along St. John-street, St. John-street-road, and Rosebery-avenue, be adopted to the reconstruction of the first sections (about 22¼ miles in length) of the Council's (northern) tramways; (*b*) that the drawings of the system of electrical traction proposed to be adopted by the Council in connection with the reconstruction of the 22¼ miles of tramways referred to in the foregoing resolution, together with a statement of the materials to be used in such reconstruction, be submitted when ready for the approval of the Board of Trade, as required by the London County Tramways (Electrical Powers) Act, 1900; (*c*) that copies of the said drawings and statement be supplied to the councils of the several metropolitan boroughs concerned in order that each of these bodies may, in accordance with the Act above referred to, have an opportunity of being heard thereon by the Board of Trade, and that a copy of the said drawings and statement be also furnished to the North Metropolitan Tramways Company. Another report was forthcoming from the Highways Committee dealing with the acquisition of property for the erection of an electricity generating station at Pimlico, which is required to supply the electric trams with energy in the western half of the county. Including the rehousing of persons displaced, the total capital expenditure on the acquisition of this property, known as the Pimlico Gasworks, will be £64,000. It is probable that the erection of the generating station will not be required to be commenced for some two years, but the committee are getting well in hand with the preparations for a suitable site. Belgian rails were again in evidence at the meeting, and Mr. J. Williams Benn had to submit to a long string of questions criticising the Council's action in purchasing their tramway rails on the Continent in preference to this country. For example, Mr. Goodrich asked the chairman of the committee whether he would say yes or no to the question whether the men engaged in the manufacture of the Belgian tramrails ordered by the Council were paid trade union rates of wages, and what method the committee had adopted to find it out. Mr. E. Collins pointed out that for some weeks he had been persistent in trying to obtain an answer to this question, but Mr. Benn had fenced with the matter and confined himself to saying that in regard to the manufacture of these rails he had had a report which was generally satisfactory. He now desired to be more definite, and would ask Mr. Benn for the name of the firm manufacturing the rails, and also whether the testing took place in Belgium or England. Colonel Rotton said that this was a subject in which the working people of this country were deeply interested, and he would now ask whether it was true that the men in Belgium worked 79 hours a week, and also in some firms on Sundays. Mr. Benn: With regard to these Belgian rails, I must refer my hon. friends to the answers I have already given. I can only say with regard to these rails, "What I have said I have said." The Highways Committee presented their report upon the regulations issued by the Board of Trade under the Motorcar Act, 1903. They recommended that the maximum fee of £3 prescribed by the Act should be charged for the assignment to a manufacturer or dealer of a general identification mark. This was adopted.

LIGHTING AND GENERAL.

Long-Distance Telephone.—We understand that telephonic communication between Liverpool and France is promised by the Post Office.

Boston.—The Council have decided to at once proceed to carry out the expiring provisional order. The cost of the scheme is estimated under £25,000.

Tredegar.—The electric light installation at Bedwellty Pits has been completed, and has proved highly satisfactory and a great boon to the inhabitants.

Whitehaven.—Twenty-one tenders for the lighting of the workhouse and infirmary by electric light have been referred to a committee of the Guardians for report, to be presented at the next meeting.

Commercial Cable Co.—The directors have declared a quarterly dividend of 2 per cent., payable on Jan. 2, 1904. The transfer books will be closed from the 19th inst. to Jan. 4, 1904, inclusive.

Chippenham.—The Rural District Council have consented to the application of the Town Council of Chippenham for a provisional order for the supply of certain rural parishes adjoining the borough with electricity.

Eastbourne.—An enquiry has been held into an application for sanction to borrow £10,000 for electric light purposes. On Tuesday the Mayor (Councillor Ashley Maude) opened an electrical exhibition at the town hall.

Swindon.—The Town Council in their new Bill ask for extension of time for authorised tramways; they also seek powers for new tramways, the extension of electricity limits, the supply of electricity in bulk, omnibuses, etc.

Tunbridge Wells.—The Town Council have received an offer from a syndicate to purchase the electric lighting works at £10,000 profit beyond the cost acready entailed by the Corporation. The cost of the works has been £80,000.

Scarborough Telephones.—At a meeting of the Telephone Sub-Committee of the Town Council on Friday specifications for a system of municipal telephones at Scarborough, received from Mr. Bennett, were referred to the borough engineer to report upon.

Western Telegraph Co.—The directors have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, for the quarter ended Sept. 30 last.

Maidenhead.—The units generated for the week ending Oct. 17 amounted to 3,284; to Oct. 24, 3,641; to Oct. 31, 3,719; to Nov. 7, 4,125; and to Nov. 14, 4,336, which show a steady increase. At present 9,000 lamps are connected for private lighting.

Lecture.—Under the auspices of the Halifax Scientific Society Mr. W. M. Rogerson, the borough electrical engineer, delivered a lecture at the Literary and Philosophical Society's rooms last week on the subject of the development and uses of electric motors.

Middlesbrough.—The engineer, Mr. H. M. Taylor, in his last report states that the income of the electric light department during 1902 was £2,167, and the costs £1,637, leaving a profit of £530. In 1903 the income had been £3,127, costs £1,758, profit £1,378.

Strabane.—With regard to the Ulster electrical power scheme, it has been decided to ask the electrical power company what powers they are seeking, and also to consult Mr. Hunt, London, as to what effect the electrical scheme would have on the Urban District Council's new gasworks.

Redditch.—At the last meeting of the Urban District Council, in moving the adoption of the Electric Supply Committee's report, the chairman spoke of the highly satisfactory results which had attended the working of the temporary steam plant which had been started working at the lighting station.

European Telegraph Rates.—According to a recent letter of the Postmaster General there is at present no prospect of the rate for telegrams throughout Europe being reduced to 1d. per word. The reductions decided upon at the recent International Telegraph Conference in London will come into force on July 1 next.

Chester.—On Friday a meeting was held with regard to the movement for the extension of the free area for telephone calls in the Chester and North Wales district. A committee was appointed to approach the various county councils in North Wales and their members of Parliament with a view to urging the Government in the matter.

The "Victory."—During Admiral Sir John Fisher's inspection of the "Victory" a week ago, it was suggested that the cockpit where Lord Nelson died should be lighted by electricity supplied from stationary batteries, so that visitors could have a better view of the place where the hero of Trafalgar breathed his last. The matter is to be considered, but nothing has been settled at present.

Colchester.—The electric lighting of Mersea, Maldon, Military, and Butt roads is to be proceeded with. The electrical engineer, Mr. Sillar, has prepared the following comparative statement: output of electricity in units during September, 1903, 43,830 (1902, 28,912; 1901, 16,500); number of consumers at end of October, 387, (300 and 202); total number of 8-c.p. lamps connected, 24,015 (18 302 and 11,642).

London County Council.—On Tuesday it was agreed to lend the St. Pancras Borough Council £23,960 for electric light installation, and the Stepney Borough Council £17,930 for the purchase of property, part of which is to be used as a site for dust destructor and electric lighting works. Notices to lay mains by the Blackheath and Greenwich District and the Metropolitan Electric Supply Companies were agreed to.

Croydon.—The engineer has reported that it is not possible to supply any more lamps from the present public lighting mains, and extensions estimated to cost £340, including provision for the supply of private consumers who might be obtained in this district, have been agreed to. It has also been decided to expend £1,188 on mains, etc, in Norbury-avenue.

Stone.—A letter was read at the meeting of the Lighting Sub-Committee from the Southern District Electricity Corporation, asking for the consent of the Council to the Corporation's application to the Board of Trade for a provisional order to supply electricity in the Council's district. The committee did not think it would be to the advantage of the Council to consent to the application, and their action was confirmed.

Farnborough.—The Board of Trade have asked with reference to the Farnborough Electric Lighting Order, 1899, whether any steps had been taken by the undertakers to carry out the proposals to transfer their powers, duties, and liabilities to Power and Traction, Limited, or to establish works under the order. The Council are replying that no formal application had been made by Power and Traction, Limited, for a transfer of the powers of the order.

Inverness.—The Town Council have accepted the draft agreement with the Edmundson Electricity Company, London, for the introduction of electricity into the town. The company is to carry out the work, which will cost at the outset £18,000. At certain periods it is within the option of the Corporation to purchase it. The Corporation are to receive £2,100, which has already been expended by them in connection with the electric lighting proposal.

Woolwich.—The Electricity Committee have appointed a sub-committee, consisting of Alderman Tynemouth, Councillors Calderwood, Fennell, Ledger, Merritt, J. Turnbull, sen., and W. Turner, to consider and report on alternative schemes of electric lighting for Eltham, an assisted wiring scheme, electricity workmen's regulations, and also to act as members of the Joint Electricity and Works Sub-Committee to consider the question of street lighting by electricity.

Prestwich.—The Lancashire Asylums Board have decided that £6,000 be granted out of the asylums fund for alterations and additions to the electric light and power plant at Prestwich Asylum, near Manchester. The plant is being extended under the superintendence of Mr. R. A. Wood, the electrical engineer. The additions include high-pressure boilers, a 250-kw. steam dynamo, and new switchboard. Power will be transmitted to outlying buildings by overhead mains.

Digitized by Google

Exeter.—At the last Council meeting a discussion took place as to the necessity for improving the lighting in various parts of the city, especially in St. Thomas. It was stated that the question could not be considered until the completion of the new electricity works, which, it was hoped, would be out of the contractor's hands by Lady Day next. The necessity for the carrying out of a scheme for the provision of a refuse destructor was also brought forward, but no action was taken.

Ramsgate.—The Corporation have accepted a bond from Edmundson's Electricity Corporation for the electric lighting of the district. The Ramsgate and District Company have agreed to insert in their order a provision for the same compulsory area as in the original Corporation order. We refer elsewhere to the support given by the Council to that company, and note that the Isle of Thanet Electric Tramways and Lighting Company, Limited, also intend to proceed with their order.

Stock Exchange.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to the Metropolitan District Railway Company's partly paid scrip of a further issue of £500,000 4 per cent. perpetual debenture stock. The committee have been asked to allow the following securities to be quoted in the official list: Blackheath and Greenwich District Electric Light Company's 50,000 7 per cent. cumulative preference shares of £1 each, fully paid.

Pollokshaws.—The Electric Lighting Committee have had an interview with representatives of the burghs of Rutherglen and Milngavie, who are interested in the proposals of the Clyde Valley Electric Power Company, and also with the directors of that company. As a result of the latter interview, the Clyde Valley Electric Power Company have made certain proposals. A deputation will also wait upon the Glasgow Corporation, and it has also been agreed to apply to the Board of Trade for a provisional order.

Ilkley.—A committee of the Ilkley Urban District Council has been authorised to recommend a site for the erection of a refuse destructor, and to prepare a scheme, including an estimate of the cost. In response to a suggestion from the National Telephone Company as to the laying of underground wires in Ilkley, it is decided to invite the manager to attend the meeting of the committee with plans of the proposals. It has been decided to circulate to the members a report of Mr. F. J. Warden-Stevens on the electric lighting.

Brighton.—Tuesday's enquiry into loans included a loan of £175 for providing 12 additional cells for the accumulation of electricity at the works in North-road in order to secure greater efficiency in the supply of current to the trams. Under the original contract 240 cells were put in, and when the Electrical Power Storage Company, who had charge of the work, were asked to estimate for the additional 12 cells they quoted £175, but only on condition that the work was put in hand while their workmen were still in the town. The work has been done already.

Ladderman's Belt.—Mr. Heathman, Parsons Green, S.W., has invented a belt which is to prevent laddermen from falling off and thus injuring themselves and their employers' pockets. This has a large snap-hook to grip the rung of any ladder, and is adjustable sideways and lengthwise, so that the worker has great freedom of movement. In fact, he can turn round with his back towards the ladder and move away if he is upon a ladder platform. These belts are manufactured at a low cost, so that expense need not retard its adoption.

Glasgow.—Upon a report of a deputation which saw the Harris Anderson water purifier in operation at the power station of the Newcastle Electric Supply Company, Limited, Wallsend, a sub-committee has recommended the adoption of the purifier for Pinkston power station. The cost of the apparatus will be between £1,400 and £1,500, and it is estimated that it will save not less than £500 a year, and remove the necessity for considering an additional water supply for the Pinkston boilers. The proposal is still under consideration.

Inventions Exhibition at Brighton.—Lady Louise Loder opened at the Brighton Aquarium last week an exhibition of inventions which has been promoted by the Corporation. Amongst electrical matters, we notice an exhibit illustrating the new telephonic system of the Corporation. The National Telephone Company also show telephones, including the new megaphone instrument for magnifying sounds, and a new fire-alarm, and there is an apparatus on the terrace destined to flash out whole sentences in electric light across the roof of the building. The exhibition will remain open until the 20th inst.

Clitheroe.—The Town Council have decided to fix their seal to the memorial for an electric lighting provisional order. Mr. Barton, electrical engineer, estimated the cost of the works at £11,260, and the borrowing powers will be fixed at £12,000. The detailed estimate is as follows: buildings £2,350 with chimney for the generating station, £1,670 for steam generating plant, £4,250 for generators, including two steam dynamos, cables, boxes, and supplies to consumers, £1,825. Approximate engineer's fee £380, travelling crane £180, and 5,000 superficial square yards of land at 1½d. per yard, at 20 years' purchase, £625 and £1,000 for contingencies, making a total of £11,260.

City of London.—At the last Court of Common Council the City Lands Committee asked the Court for authority to enter into an arrangement with the Charing Cross and Strand Electricity Supply Corporation, Limited, to supply the current (at a pressure of 200 volts) to buildings under the control of the committee, at the rate of 3d. per Board of Trade unit for lighting, and 2½d. for motive power, for a period of five years. After discussion the following amendment was carried: "That the whole matter be referred back to the City Lands Committee, with a view to enabling the City of London Electric Lighting Company, Limited, to have the opportunity of tenderngi as well as the Charing Cross and Strand Electricity Supply Corporation, Limited."

Hampstead.—At the last Council meeting it was stated that on the previous evening the electric light in one of the busiest portions of the High-road, Kilburn, had failed. The electrical engineer reported that the failure was due to a defective cable, which was part of a consignment supplied some years ago, and, in some parts of the borough, had been renewed. For a certain distance in the High-road it had not been renewed, and the consequent failure on two occasions had caused the greatest inconvenience to shopkeepers in that busy thoroughfare. The Lighting Committee were instructed to bring up a report and estimate for taking out the length of defective cable and replacing it with a new one.

Beckenham.—The Council last week considered a letter from the Board of Trade regarding the proposed purchase of the Crystal Palace District electric lighting order by the Blackheath Electric Light Company, Limited, and the proposed change in the system of supply. The Clerk stated that they had powers under this order to take over that part of the parish of Beckenham included in the Crystal Palace order. The year 1905 would be the last for taking over that district. The system used in the Crystal Palace district was similar to that in Beckenham. It was most important, therefore, that the proposal of the company should not be sanctioned until Beckenham had had an opportunity of considering whether they would take over the district. It was decided that the Board of Trade be informed that the Urban District Council were considering whether they would take over the district or not, and also that the matter be referred to the Electric Lighting Committee, and that the surveyor and consulting electrical engineer be asked to advise them in the matter.

Halifax.—The new plant now being introduced at the main electricity works is expected to be ready for use in about two weeks' time. It consists of a 1,200-i.h.p. horizontal engine, made by Messrs. Pollit and Wigzell, of Sowerby Bridge, coupled to a 750-kw. dynamo, supplied by the Electric Construction Company, of Wolverhampton. The cost is about £8,000, and was necessitated by increased applications for current for lighting and power purposes, as every machine is now running at full load. In addition to meeting these requirements, it will be possible, when the scheme is completed, to give the extra supply that is needed for the tramways. The work of erecting the new electrical sub-station at Hipperholme was commenced on Monday. This undertaking has been decided upon in order to save the expense of running a low-tension cable all the way to Brighouse for the purpose of supplying power for the tramways extension to that town. When this scheme is completed the Corporation will be in a position to give the Hipperholme district a full supply for lighting and power purposes.

Newcastle Infirmary.—The electrical equipment which is being placed in the new infirmary by the contractors, Messrs. Falconar, Cross, and Co., is being carried out in accordance with specifications prepared by Messrs. Dolby and Williamson, and includes, besides motors for driving the various power-using machinery, over 2,000 incandescent electric lights, also a complete system of telephones, electric bells and fire-alarms, electric clocks, and electro-medical appliances. There will be about 50 electric clocks spread over the whole of the building, all controlled from a master clock. The current will be supplied from the mains of the Newcastle and District Electric Lighting Company. The laundry, kitchen, and other machinery will be driven by electric motors, together with lifts for various purposes, and there will be a complete system of ventilation by means of electric fans. The whole of the wiring is being carried out in smooth-drawn welded steel tubes, fixed together with screwed unions; these tubes are in most instances sunk beneath the plaster work, and draw-in or inspection boxes are fitted at intervals with the covers made accessible and marked in a conspicuous manner, so that if necessary the whole of the sectional wires can be withdrawn.

London Gazette.—A second and final dividend of 10s. in the £ (making a total of 20s. in the £) has been declared in the estate of John Frederick Worthington, electrical engineer, Foundry Works, Foundry-street, Hanley, Stafford, payable now at the offices of Poppleton and Appleby, 26, Corporation-street, Birmingham. The creditors of the Electric Tramways Trust, Limited, are required by Jan. 1 to send their names and addresses and particulars of debts or claims, to Leslie Morse, 32, Queen Victoria-street, E.C., or Reginald Albert Goodman, Granville House, Arundel-street, Strand, W.C. The first meeting in the estate of George Neale, lately trading with John Carnaby as South-Western Electrical Contracting and Maintenance Company, electricians, 2, Fulham Palace-road, London, has been held. A dividend will be declared in the estate of John Pierrepont Child, electrical engineer, 150, Powis-street, Woolwich, and 109, Piedmont-road, Plumstead, Kent. Last day for receiving proofs, Dec. 15. Alexandra Mackintosh, official receiver, 24, Railway-approach, London Bridge. The first meeting in the estate of Cecil Wray, mechanical and electrical engineer, 16, Chevin-view, Ecclesfield, lately of 24, Simes-street, Bradford, will be held on Dec. 10, at 3 p.m., at the official receiver's office, 29, Tyrrel-street, Bradford. A receiving order has been made out in the estate of John Webster Storr, electrical engineer, 29 Grange-road, Dudley, Worcester. The first meeting in the estate of Hooley, Talbot, and Co., electrical engineers and contractors, Regent-street, Rugby, Warwick, will be held on Dec. 7, at 12 noon, at the official receiver's office, 17, Hertford-street, Coventry.

Gravesend.—The resident engineer in his report of working for three months ended Sept. 30, supplies the following figures: units supplied to tramway company, 107,777; units supplied to private consumers, 18,290; units supplied to public lighting, 14,270; units supplied to works, 5,078; units unaccounted for, 14,872; units generated, 160,287. Number of consumers connected and applied, 127; increase over last quarter, 29; equivalent number of 8-c.p. lamps, 7,467; increase over last quarter, 1,592. A letter from the Northfleet Urban District Council referring to correspondence on the Northfleet electric lighting is under consideration. The document states that owing to the limitations to the Council's powers imposed by Section 11 of the Electric Lighting Act, 1882, the

Digitized by Google

Electric Lighting Committee of the Northfleet Council have come to the conclusion that no satisfactory arrangement can be made with any other corporate body, company, or person for the maintenance and execution of electric light works within their district, and have accordingly advised the Council to intimate to all persons who have been in communication with them upon the subject, that the Council will assist (at the expense of the promoters) in the promotion in Parliament of a supplemental or fresh electric lighting provisional order for the district, provided the undertakers contribute £250 to cover the expenses incurred by the Council in obtaining their existing order. Finally, the Corporation of Gravesend are asked whether they would be disposed to make an offer to the Council on these lines.

Islington.—The Council have agreed to carry out extensions to mains at £825, and to purchase from 70 to 100 services at an average cost for cable and labour of about £8 each, say £600; house terminal boxes, including compound and fuses, 75 at 16s., £60; service boxes for rubber cables, and junction boxes for paper cables, 40 at £5. 5s. each, £210; brick pits, etc., for junction boxes. 10 at £5 each, £50; buried service boxes for paper cable, 20 at £2 each, £40; jointing material, filling, connections, and reinstating on buried boxes for paper cable, £26; high-tension feeder boxes, two at £15, £30; special meters at Marlborough Theatre, six 150-ampere 200-volt meters at £5. 5s. each, £31. 10s.; six 150-ampere 200-volt indicators at £2. 15s each, £16. 10s.; two jointers' tents at £5 each, £10; sundry jointing material, small tools, repairs to gas services, insulating enamel, etc., £26. It is proposed, in order to facilitate supply to new customers, to submit an estimate each half-year so that the necessary expenditure for service line, terminal boxes, trenching, relay, fuse boxes, meter fixing, and other incidental works, amounting in the case of any consumer to less than £50, may be provided for. In the event of the London County Council sanctioning the borrowing of £849 for electric lighting purposes for a period of 42 years, the Borough Council propose to undertake that during the currency of the loan no further loans will be raised to replace any of the plant and machinery, the cost of which is to be defrayed out of such loan, and that any renewals required during the period thereof shall be provided out of a sinking fund to be created for the purpose or from maintenance account.

Parliamentary Notices.—Amongst the proposed new Bills for session 1904 we note Leicestershire and Warwickshire Electric Power, by company of same name. Objects: extension of periods limited by the Leicestershire and Warwickshire Electric Power Act, 1902, for commencing the works and for providing the generating stations prescribed by that Act, and also for the removal of restrictions as to erection of generating stations on lands acquired by agreement under that Act; amendment of borrowing powers of company under Act of 1902; power to acquire electric undertakings by agreement; payment of interest out of capital; application of funds; incorporation and amendment of Acts. Ulster Electric Power, by company to be formed. Objects: incorporation of company; power to establish generating stations and works, and supply electricity, etc., in the counties or parts of the counties of Down, Antrim, Londonderry, Donegal, Tyrone, Fermanagh, Armagh, Monaghan, and Cavan, and the county boroughs of Belfast and Londonderry, all within the province of Ulster; compulsory purchase and user of lands, etc.; power to take parts of property and exemption from Section 92 of the Lands Clauses Consolidation Act, 1845; special powers as to capital and borrowing, breaking up of streets, roads, etc., and power to lay down wires, pipes, etc., and exercise of other powers, rates, charges, etc.; exception from certain sections of Electric Lighting Act, 1882, and of the schedule to the Electric Lighting (Clauses) Act, 1899; provisions as to supply; agreements with and powers to local authorities, companies, and bodies; payment of interest out of capital during construction; incorporation and amendment of Acts, etc.

Natal Harbour Department.—The officials ruling the destiny of the Natal Harbour Department have just given an order for the lighting of the suction dredgers "Curlew," "Ibis," and "Water Rat" by electricity to enable them to work by night in Durban Bay. Tenders were informally called for, and Messrs. Greenwood and Batley, Limited, of Albion Works, Leeds, through their direct representative, at present in Durban, were successful in securing the order. The plant which will be supplied consists of three complete sets of 7-b.h.p. 4·4-kw. De Laval patent steam turbine-dynamos, arranged to work either condensing or non-condensing at a steam pressure of 50lb. and 110lb. per square inch, two being designed for the latter pressure. The voltage of the dynamos will be 110, and the capacity of each of the sets is equivalent to about 140 8-c.p. incandescent lamps. The De Laval turbine is extremely applicable for this class of work, where economy in space is a great desideratum, this feature being largely responsible for the installation of upwards of 5,000 h.p. in small sets of 1½ h.p. to 30 h.p. in vessels all over the world, including cruisers, torpedo boats, torpedo-boat destroyers, gunboats, liners, tugs, etc. For example, the 7-b.h.p. type weighs only 8cwt., and occupies a space of 5ft. by 2ft., being 2ft. 6in. high, and being also self-contained requires little foundation beyond a wooden bench. The installing and wiring of the dredgers will be done departmentally under the supervision of Mr. G. Stobie, A.M.I.E.E., the harbour electrical engineer. He may be considered the pioneer of steam-turbines in South Africa, having installed one of the first of the De Laval type imported. The work is to be commenced about the middle of December, and will be completed early in the New Year.

St. Marylebone.—Amongst the motions not reached at last week's meeting was a notice to the effect "That a return be presented to the Council showing (1) the total cost of obtaining the Act of Parliament authorising the Borough Council to negotiate for the purchase of the Metropolitan Electric Supply Company's Marylebone undertaking; (2) the entire cost of the arbitration, specifying (*a*) the amount paid to the arbitrator, (*b*) counsel engaged and fees paid to each, (*c*) professional witnesses engaged and fees paid to each, (*d*) payment to solicitors and general charges, (*e*) amount paid to electric company for their costs in the arbitration; (3) costs incurred (*a*) by the Borough Council, (*b*) by the Metropolitan Company as taxed in the action for specific performance before Mr. Justice Buckley stating if the Borough Council had to pay costs of both parties, (*c*) amount to be paid to the company for works executed since the appointed day for taking over the concern; (4) amount of counsel's fees for opinions and consultations and other fees and expenses paid or to be paid by the Borough Council up to the end of October, 1903; (5) total amount paid by the Borough Council or to be paid (including salaries, which are to be specified) to the end of October, 1903, in connection with and in consequence of having obtained the abortive Act of Parliament; (6) from what fund all these expenses are paid." Also, "That a committee, consisting of the Mayor, Councillor J. Watson, and Councillor Edward White, be appointed to confer with the Metropolitan Electric Supply Company with a view to an arrangement being arrived at to remove the present deadlock"; and, further, "That the engagement of Mr. Arthur Wright, the electrical expert, be determined, and that the necessary notice be given him for terminating his engagement."

Electrical Machinery.—A large number of gentlemen connected with collieries, shipyards, and engineering establishments in the Northern Counties visited the works of Messrs. E. Scott and Mountain, Limited, Close, Newcastle, on Saturday last to inspect some new electrical machinery which that firm has recently completed. The chief item of interest was an enclosed three-crank compound steam-engine of 400 i.h.p., fitted with one high-pressure cylinder, 16½in. diameter, two low-pressure cylinders, each 18½in. diameter, with a stroke of 10in., this engine giving the horse-power stated above, with a steam pressure of 100lb. per square inch when running at a speed of 350 revolutions per minute. This engine is fitted with the firm's latest system of forced lubrication, which consists of a valveless oil pump delivering oil to all bearings and working parts, and is complete with powerful crankshaft governors and steam separator. The engine is direct coupled to one of the firm's three-phase alternators, constructed to give an output of 250 kw. at a pressure of 500 volts per phase, with a frequency of 50 cycles per second, this generator being of the revolving magnet type, with stationary armature and direct-coupled exciter. The whole plant is of massive construction, and weighs in all about 40 tons. The engine and generator mentioned above have been built to the order of Messrs. Bolckow, Vaughan, and Co., Limited, and will supply current to one of Messrs. Scott and Mountain's three-phase induction motors of 100 effective horse-power, which is driven by ropes on to one of the same firm's three-throw horizontal ram pumps, fitted with gunmetal rams, each 10in. diameter, with a stroke of 15in., and delivering 500 gallons per minute against a vertical head of 400ft. There was also on view plant constructed to the order of the Harton Coal Company for their Bolden Colliery, near Sunderland, and of the Northern Counties Electricity Supply Company.

Brighton Telephones.—The agenda for last night's Town Council meeting shows that at the meeting of the Telephones Committee on Friday last the Mayor submitted to the committee the correspondence between himself and the secretary to the National Telephone Company concerning Councillor Carden's action at Burgess Hill and alleged unfair preference. In addition, the Town Clerk submitted a letter from the Postmaster-General's Department enclosing copy of a letter addressed to the Department by the National Telephone Company and asking for the Corporation's observations thereon. Mr. Gaine's letter to the Post Office recapitulates the points already published, and adds: "I am directed in particular to call the attention of the Postmaster-General to the fact that not only is money being paid by or on behalf of the Corporation to induce these subscribers to break their contracts with the company, but also that these subscribers are offered a preference over other subscribers in the area inasmuch as the Brighton Corporation is offering to supply them with a free service for a certain period of time. The company is advised that these proceedings by or on behalf of the Corporation constitute a clear breach of the undue preference provisions of its license, and I am directed to ask that the Postmaster-General will take immediate and effective action in the matter." The committee resolved: "That the Postmaster-General be informed that the Council endorse the observations contained in the Mayor's letter to the manager of the National Telephone Company of the 17th inst., and, in addition to what is stated by the Mayor on the subject of the alleged preferential treatment, they would point out that the terms offered to subscribers in the Brighton area are the same as those given in Portsmouth, Glasgow, Swansea, and other towns where corporation telephones have been established, and by the Post Office Department in the case of London."

Liverpool.—Mr. A. B. Holmes, consulting electrical engineer to the Liverpool City Council, has prepared a report on the Corporation electric supply stations and plant, in which he points out that the demand for electrical energy for power and lighting continues steadily to increase, and it is estimated that the output of the supply stations for 1903 will exceed that of the previous year by the following percentages: lighting, 20 per cent.; power, 60 per cent.; and tramways, 5 per cent. The connections to the supply mains for lighting and power (exclusive of tramways) at the commencement of the current year were equivalent to 221,000 c.p. incandescent lamps, and it would be necessary for the Electric Supply Committee to consider what extensions would be required to meet the demand for electrical energy which might be anticipated in 1904 and 1905. No more steam plant could be installed in the existing power stations in the central districts, and no suitable site was obtainable in these districts for another large steam station, by means of which the simplicity and economy of the generation of energy at the pressure of distribution to the consumer could be secured. It was consequently necessary to bring in an additional supply at high pressure from Lister-drive. His proposals are as follows: (1) at Fairclough-lane, an addition to the building and 2,000 kw. transforming plant; (2) at Oldham-place, an addition to the building and 2,000-kw. transforming plant;

Digitized by Google

(3) at Rice-lane, the construction of a sub-station to contain transforming plant of 800 kw.: (4) at Cobbs Quarry, 800-kw. transforming plant; (5) also transforming plant at Smithdown-road. It would also be necessary to order the boilers, engines, generators, and accessories for the equipment of the second section of the Lister-drive station. It was not anticipated that any addition would be required at the Gateacre and Garston stations to meet the ordinary increase in demand for 1904, but for tramway extensions in these districts further generating plant would be necessary.

Wrexham.—At a recent meeting of the Electricity Supply Committee the borough accountant and the electrical engineer were asked to go fully into the question of revising the scale of charges for the supply of electricity in any manner, and report to the next meeting any recommendations they may consider requisite to enable the committee to come to a conclusion as to whether the present scale should be varied or otherwise. A letter was read from the St. Helens Cable Company, pointing out that under their original contract they had undertaken to maintain the cables for a period of about 12 years from the present date. Since the entire replacement of the distributing and arc cables there had been a complete absence of breakdown, only two or three trifling repairs being necessary. On every cable system containing a number of small cables there were slight repairs to be done every few months. This was usually carried out by the town electrical engineer as part of ordinary work. In repairing such defects at Wrexham the company were put to the additional expense of travelling and out allowances, besides the great inconvenience of finding an engineer to send at a few hours' notice. They therefore proposed that they compound the maintenance by a payment of £200, this amount being that which they might have to spend, whereas the Corporation engineer, being on the spot, would not spend a quarter of it. The proposal was referred to Mr. Trentham, consulting engineer, and to the borough electrical engineer for a confidential report as to whether it should be entertained. The borough electrical engineer reported that the units generated in October, 1903, were 44,394; 1902, 20,486; used for tramways, 14,764; used for lighting and motors, 29,630. Three consumers had been connected during the month, 133 lamps of 8 c.p.; corresponding month last year, 113 8 c.p. Total number of 8-c.p. lamps connected to date for private supply, 11,007. A statement is to be furnished to the committee quarterly showing the cost of generating electricity. The engineer also stated that, owing to the floods of Oct. 27, the engines were stopped from 9.50 p.m. to 10.50 p.m., the flywheels being 6in. under water. The supply was taken up satisfactorily from the accumulators. The water rose to within 1in. of the magnets, and 15in. or so up the main switchboard, rendering it dangerous. Some of the lower cables were fired. The condenser and its electric motor were immersed for two days, and rendered useless. The water burst from the brook in several places. The damage, estimated at £40, was repaired forthwith by Messrs Lewis Bros. The borough surveyor has been requested to report as to what would be necessary to prevent water backing up and flooding the depôt premises in times of storm. The Council intend to advertise for a pupil at a premium of £75, payable by three annual instalments, and half of such premium is to be paid to the electrical engineer. The Electricity Committee have prepared a scheme for the extension of the lighting cables, to cost £4,500, but it was referred back for further consideration.

PROVISIONAL PATENTS, 1903.

Nov. 23.

25473. Improvements in sensitive hot-wire voltmeters. Richard Threlfall, 30, George-road, Edgbaston, Birmingham.

25482. Improvements in or relating to apparatus for obtaining variable electrical ignition, applicable to gas-engines. Levi Mellor, 4, St. Ann's-square, Manchester.

25525. Improvements in electric starting switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25526. Improvements in speed-limiting devices. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25527. Improvements in train-control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25567. Improved process and apparatus for producing a shifting of phase of 90 degrees in alternating-current meters. Emanuel Morck, 46, Lincoln's-inn-fields, London. (Complete specification.)

25571. Improvements in or relating to electric lamps. Walter Charles Head, William Arthur Snape, and Robert Volland, 173, Fleet-street, London.

25573. Improvements connected with the adjusting mechanism of electric arc lamps used with cinematograph and other apparatus. Herbert James Dawson, 173, Fleet-street, London.

25577. Improvements in electric arc lamps. William James Davey, 40, Chancery-lane, London.

Nov. 24.

25591. Improvements in induction coils and transformers. Vernon Warburton Delves-Broughton and John Austin Cole, 80, Central-hill, Upper Norwood, London.

25677. Improvements in protecting electrical windings from static strains. John Pearson, Frederick Richard M. Cutcheon, and James Franklin Williamson, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

25633. Improvements in electric arc lamps. John William Ewart, 36, Chancery-lane, London.

25638. Improvements in surface condensers for elastic-fluid turbines. The Warwick Machinery Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25657. Improvements in lightning arresters or devices for preventing overcharging in electric conductors. Georg Zapf, 6, Lord street, Liverpool.

25663. Improvements in telephone systems. Falk, Stadelmann, and Co., Limited, and Louis Thurnauer, 4, South-street, Finsbury, London.

25669. Improvements relating to electric conductors or cables. Sidney George Brown, 45, Southampton-buildings, Chancery-lane, London.

25698. Improvements in bodies adapted for lighting purposes and rendered incandescent by heat or electricity. John Haskins Ladd, 11, Southampton-buildings, Chancery-lane, London.

Nov. 25.

25704. A carbon-break fuse. Archibald Johnston and Stephen George Martin, St. Helen's Depôt, Swansea Tramway Company, Swansea.

25725. Improvements in electric signalling for electric railways and street tramways. Hugh Innes Rogers, Edward May Munro, and Henry Brecknell, Thrissell-street, Bristol.

25741. Improvements in glow lamp holders. Philip Braham, 18, Leigh-street, London.

25765. Improvements relating to electrical recording apparatus. Doningo Cervera, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

Nov. 26.

25792. An improved method of agitating solution in order to quicken the electrolytic deposition of metals. John Speed, 6, Kirby-street, Hatton-garden, London.

25814. Improvements in trolley heads for electric tramcars. Wilhelm Willenbücher, 51, Deansgate-arcade, Manchester. (Complete specification.)

25847. An improvement relating to dynamo-electric generators and motors. Joseph Daniel Rowbotham Blain, 13, Meadrow, Godalming, Surrey.

25848. Improvements in apparatus for measuring speeds of rotation. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25849. Improvements in electric rheostats The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25850. Improvements in time-limit devices for electric switches and the like. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25851. Improvements in methods of operating repulsion motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25852. Improvements in methods of exhausting vapour conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25853. Improvements in insulating material for electric conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25854. Improvements in suspenders for overhead electric conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25855. Improvements in electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25856. Improvements in automatic air-brake systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25857. Improvements in tube-coating machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25858. Improvements in windings for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25870. Improvements in or relating to electrolytic electricity meters. The Bastian Meter Company, Limited, Charles Orme Bastian, and Charles Henberow Churchill, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

25885. Improvements in apparatus for securing shades, reflectors, and the like to electric incandescent lamps. Henry Wollenden, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

25886. Improvements in or connected with coin operated or controlled electricity meters. John Reid Dick, Norfolk House, Norfolk-street, Strand, London.

Digitized by Google

25887. Improvements connected with controllers for regulating the speed of electric motors. William Harding Scott, 47, Lincoln's-inn-fields, London.

Nov. 27.

25925. Improvements in electrical resistances. Percy Macaulay Ashworth Matthews, 9, Teneriffe-street, Lower Broughton, Manchester.

25937. Improvements in or relating to accumulators. Alfred Blackman, St. Brelade, Glamorgan-road, Hampton Wick, Middlesex.

25955. An improved electric safety switch-wedge. Henry John Leeves-Johnson and Maurice Moser, 55, Chancery-lane, London.

25969. An improved safety device for use in electric traction on the contact-stud system. William Griffiths and Benjamin Harry Bedell, 22, Southampton-buildings, Chancery-lane, London.

25970. Improved current collector for use in stud-contact systems of electric traction. William Griffiths and Benjamin Harry Bedell, 22, Southampton-buildings, Chancery-lane, London.

25990. Improvements in and pertaining to electrical brush-holders. Henry Alexander Mavor and Mavor and Coulson, Limited, 46, Lincoln's-inn-fields, London.

Nov. 28.

25994. Electrical shade-ring forceps. Thomas Dow Frew, 2, King James-place, Perth.

26005. Apparatus applicable to gas, electric, and other stoves. Joseph Fearnhead, 17, Mawdsley-street, Bolton.

26051. Improvements relating to voltage-regulating devices for alternating-current electric lines. Giorgio Finzi, 45, Southampton-buildings, Chancery-lane, London.

26058. Improvements in high-voltage spark arresters. James Yate Johnson, 47, Lincoln's-inn-fields. (The Elektrizitäts-Aktien-Gesellschaft vormals W. Lahmeyer und Co., Germany.) (Complete specification.)

26067. Improvements in advertising appliances, applicable for use in connection with telephones, and for other purposes. Percy Fullerton Corkhill, 6, Lord-street, Liverpool.

26069. Improvements in and relating to multiple electric motor control. Thorsten von Zweigbergk, 18, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 17, 1903.

1902.

25554. Electric contacts. De Kando.

25731. Electro-mechanical regulators. Routin.

27757. Electric heaters. Carolan. (General Electric Company.)

27767. Electric arc lamps. Carolan. (General Electric Company.)

27770. Electric arc lamps for constant potential circuits. Carolan. (General Electric Company.)

28728. Fusible safety devices or cut-outs used in connection with electricity systems. Macgregor.

28820. Electrodes for primary batteries. Mann and Goebel.

1903.

47. Construction of current transformers used in conjunction with instruments measuring the energy in alternate-current electric circuits. Heap.

70. Electromagnetic apparatus in which the armature is to be turned into different positions, particularly applicable to electromagnetic switches. Siemens Bros. and Co., Limited, and Ferreira.

329. Method of and means for regulating electric motors. Lang.

455. Control of direct-current dynamos and motors. Javaux and Barbou.

1064. Electric switches. Carolan. (General Electric Company.)

1095. Electric lighting systems. McElroy.

1132. Cord grips and means for holding and securing cords and wires, intended more especially for securing flexible electrical conductors to electric lamp-holders and electric supply fittings. Dixon.

1299. Safety appliances for the prevention of injury where a trolley line or other live conductor breaks. Stewart.

1416. Miners' electric lamps. Prested.

1949. Surface-contact structures for electric railways and tramways. Carolan. (General Electric Company.)

2030. Couplings for metal tubes containing electric wires. Barber.

2060. Automatic electric lift gate lock. Chaudoir and Caston.

2198. Automatic electric switches. Bloxam. (Ellison.)

2961. Electrically-actuated semaphores. Siemens Bros. and Co., Limited, and Ferreira.

3873. Electric resistances and the like. Le Roy.

3986. Electric telegraph apparatus. Vanzetti. (Levy.)

5619. Electrical connection between terminal and trolley head of electric tramcars. Birkby.

8259. Systems of electrical distribution. Slaughter.

7026. Apparatus for detecting whether railway or like points are in their correct position, and an electrical switch for use therewith. Siemens Bros. and Co., Limited, and Ferreira.

8436. Permanent magnet electric generating machines. Somerville, Hicks, and Howard and Bullough, Limited.

15831. Apparatus for use in welding railway rail-joints by electricity. Kleinschmidt.

17367. Safety devices for strong-current overhead conductors. Van der Valk.

18680. Means for controlling electrically-operated elevators. Eriksen and Koefoed, Hauberg, Marstrand, and Helweg, Aktieselskabet Titan.

18755. Electrical indicating apparatus for communicating and recording instructions. Blender.

19540. Electrically-operated and controlled railway signals. Peters and Hellingson.

20155. Electricity meters. Rieunier. (Date applied for under International Convention, Oct. 2, 1902.)

22643. Brush-holders for dynamo-electric machines. Thompson.

22664. Contact apparatus for electric relay master clocks. Imray. (Siemens-Schuckertwerke G.m.b.H.).

22785. Storage battery plates. Smith. (Date applied for under International Convention, Sept. 10, 1903.)

23043. Magnetic compasses. Whyte.

23151. Method and apparatus for producing a suitable circulation of the electrolyte in electrolytic processes. Koller and Askenasy.

23225. Electric lamp sockets. Goehst.

NOTES.

University College, London.—It is stated that an anonymous donor has, through Prof. Starling, presented £50,000 to University College, London, to be applied to the promotion of higher scientific education and research.

Incorporated Municipal Electrical Association. We are notified of a change of address of the secretary of the above association. In future all communications should be addressed to Mr. C. McArthur Butler, Staple-inn-buildings South, Holborn, London, W.C.

The Nobel Prizes.—It is reported that M. Henri Becquerel, the discoverer of the rays associated with his name, will, with Madame Curie and her husband, share the Nobel prize in physics, and that Prof. Finsen, inventor of the light cure for lupus, will take the award in medicine. The awards have not yet been officially announced, but were to have been made last night at a meeting of the Scientific Academy in Stockholm. Each prize is of the value of £8,000.

Standard Gauges.—A demand has arisen for the testing, for use in mechanical engineering, of standard gauges in the forms of external and internal cylindrical steel gauges, limit gauges based on the measure of the inch and the millimetre, and other forms of gauges, verniers, micrometer-callipers, etc., included in the measuring equipment of workshops. The Board of Trade announce that the Standards Department is equipped with means for testing such gauges, provided that they are of legal and recognised denominations.

Radium Supply. — Prof. Himstedt, of Freiburg, is stated to have made an interesting discovery as to the probable supply of radium, which seems to show that its existence is far more extensive than at present known. The professor's experiments are said to have proved that all products from water and petroleum wells yield a heavy specific gas, closely resembling and probably identical with the emanation of radium, whence he concludes that a very large number of bodies are imbued with the quality of emitting a kind of Becquerel rays.

The Electro-Chemical Trade.—It is reported that the trade war between English, German, and American manufacturers of bleaching powder, which has severely depressed the industry during the past 12 months, has been ended, a working agreement having been arranged. The effect of this is already evident, the price of bleaching powder having risen to from £4 to £5 per ton, as against anything from £2 upward. The companies which have suffered most severely from the war are the Electrolytic Alkali Company, Castner-Kellner Alkali Company, and the United Alkali Company.

Electro-Harmonic Society.—The committee of this society have decided to make a change which they believe will be unanimously approved by the members—*i.e.*, to hold the smoking concerts on Dec. 18 and March 25 in the King's Hall of the Holborn Restaurant, instead of in the Crown Room as previously arranged. The concert fixed for Jan. 22 will, however, take place in the Crown Room owing to other arrangements having been made for the larger hall on that night. Seventy-eight new members have already been elected during this season, and the committee anticipate that the change mentioned will result in a further accession to the membership of the society.

Birmingham Local Section.—This section of the Institution of Electrical Engineers opened its winter session last week, when Mr. J. C. Vaudrey, until lately electrical engineer to the city of Birmingham, gave his inaugural address. In it a strong point was made of the advantage of having a common home for all the technical associations and scientific societies in the Midlands. On this subject we have written a good deal and Mr. Vaudrey has taken the matter up for the Birmingham district with considerable vigour. In his address he pointed out the advantage of having a well-stocked technical library at the disposal of the members of all such associations, and also the benefit of a common organisation. We trust that the scheme proposed will be carried through, and that Mr. Vaudrey will now have time to give his personal support to the object in view.

Electricity in the U.S. Navy.—The naval authorities in the United States are showing every desire to be abreast of the times in replacing hand and mechanical operations by electrical methods on board ship. For some time the ventilation of most of the vessels in the American fleet has been carried out by electric fans, which have supplanted the old steam-driven fans, and a new departure is soon to be made with the adoption of electrically-operated water-tight doors. The particular type to be adopted has not yet been approved, but experiments are in progress, and it is expected that a satisfactory equipment will be found before long. Further, the authorities have been investigating several types of electrical steering gear, one of which is to be adopted on board the "Nevada" as an experiment. This is quite a new application of electricity so far as warships are concerned, although we believe the British Admiralty has been experimenting recently with a certain type of electrical steering gear, with what results, however, is not known.

Royal Institution.—We understand that Prof. L. C. Miall has been elected Fullerian Professor of Physiology at the above institution. The following are the lecture arrangements at the institution before Easter so far as they are of interest to the profession: three lectures on "Electrical Methods of Measuring Temperaure," by Prof. H. L. Callendar, and six lectures by the Right Hon. Lord Rayleigh on "Physics." During the season 1904 the lectures on Tuesdays and Thursdays will be delivered at five o'clock and the Saturday lectures at three o'clock. The Friday evening meetings will begin on Jan. 15, when a discourse will be delivered by the Right Hon. Lord Rayleigh on "Shadows." Succeeding discourses will probably be given by the Rev. Walter Sidgreaves, Mr. D. G. Hogarth, Mr. H. Brereton Baker, Mr. Alexander Siemens, Prof. W. Stirling, Prof. F. T. Trouton, Prof. Dewar, and other gentlemen. Dr. Andrew Carnegie, Mr. J. S. Curgenven, Dr. J. Emerson Reynolds, and Mr. R. Wissmann have been elected members of the institution.

Electric Lighting of Trains.—On the Western Australian Government railways the electric light has been employed for illuminating the carriages for some two or three years with satisfactory results all round. The system is gradually being extended to all the rolling-stock, and, as a consequence, the annual cost of upkeep is decreasing proportionately. The report of the Acting-General Manager of Railways of West Australia for last year shows that altogether some 70 carriages have been equipped with the electric light, and on the average 47½ were maintained for the full 12 months. The cost of upkeep is stated to be £892. 9s. per annum, an average of £18. 16s. per car, as compared with £20. 12s. per car in the preceding year. The reduction would appear to be consequent upon the larger number of carriages in use than in the previous year, when an average of only 26 carriages was maintained. There seems to be some little difference of opinion as to whether a comparatively inexperienced person, or ordinary mechanic, is or is not capable of satis-

Digitized by Google

factorily attending the electric light. Enquiries, however, are to be made as to the practice where the light is in use elsewhere, which will no doubt settle the question.

Glasgow Corporation Telephones.—The committee of the Glasgow Corporation which is responsible for the municipal telephone undertaking in that city, is taking a right and proper course in regard to the undisguised hostility which is entertained in certain quarters against the municipal system, as exemplified in the articles condemnatory of the accounts which have appeared in certain electrical and engineering journals. Reprints of these, together with pamphlets, have been extensively circulated in Glasgow by anonymous agencies. The matter was before the committee at their last meeting, and, after consulting with their auditors, the committee decided to take no action, adopting the view that the accounts, having been drawn up in the form recommended by an eminent and independent firm of auditors (who certified them as correct, and after reading the articles in question had no amendments to suggest), and having been adopted, after careful consideration, successively by the Sub-Committee on Finance, the Telephone Committee, and the Town Council, call for no defence "against articles written in such obvious ignorance of the conditions which prevail in Glasgow, and with such apparent bias and purpose."

Telephones in Liverpool.—At the last meeting of the Liverpool Engineering Society Mr. C. J. Hidden read a paper on the development of the telephone in recent years. He described in detail improvements that have been made in the course of changing over old installations from the single-wire and earth system to the all-metal circuits with two insulated conductors to each subscriber. In the course of his paper he referred particularly to the work in Liverpool, where an extensive system of underground cables is being installed. The existing switchboards have also had to be altered to meet the large number of subscribers who have to be dealt with. The new exchange for the centre of the town has been laid out to accommodate 10,000 subscribers, and is complete with every modern accessory. The new multiple boards are so arranged that they can be conveniently converted in time to come to the central battery system with but slight alteration. The precautions against fire were described in detail, and the importance of this feature was emphasised. Owing to the inflammable nature of the bulk of the material used in telephone exchanges, the need for such precautions is imperative. In the course of the discussion the advantages of subways for the cables instead of conduits was taken up, but, as the author pointed out, the difficulty and cost of constructing these subways in Liverpool would be very great.

The Late Sir Frederick Bramwell.—Sympathetic tributes were paid to the memory of the late Sir Frederick Bramwell at a general monthly meeting of the Royal Institution on Monday. The Duke of Northumberland (the president) was not able to be present, but he sent a letter expressing his deep sense of the loss the institution had sustained in the death of "our respected and valued friend." His Grace continued: "His great talents and high professional reputation are known to all the world—the deep interest he always displayed in the work of the Royal Institution, and the conspicuous services he rendered it, cannot, I think, fail to be within the cognisance of every member. But it is only those who have taken part as his colleagues in the management, and who have had the privilege of enjoying his personal friendship, who can be fully aware of his genial kindliness, his wise counsels, and his indefatigable energy." The resolution, which was unanimously passed by the meeting, after placing on record the loss to the institution by the death of the deceased baronet, states that "his personality and the signal services he rendered to the institution by his unvarying devotion to and deep interest in its welfare, and in the advancement of experimental research for 27 years as manager, honorary secretary, and vice-president, will be long remembered. The managers desire to offer Lady Bramwell and her family the expression of the most sincere sympathy with them in their bereavement."

Telegraphic Communication with the North.—The Association of Chambers of Commerce, which has been chiefly instrumental in urging the Post Office to lay a complete system of underground telegraph cables to the North of England, has succeeded in eliciting some important information from Lord Stanley as to the progress which the work is making. The present state of the scheme may be concisely stated thus: The temporary wires in the pipes between Birmingham and Warrington are being replaced by a permanent cable. Seventy miles of this cable have been drawn in, and when the remaining 12 miles are drawn in there will be a permanent underground system between London and Birmingham, Manchester and Liverpool. There are already underground wires between Warrington and Manchester and Liverpool. The laying of the pipes north of Warrington to Carlisle has been finished, and temporary wires have been drawn in as far as Wigan, and will be continued to Preston. A permanent cable to Carlisle will be provided later. In Scotland it has not been possible at present to undertake more than one section of this work. That section is over the Beattock incline, where the overhead wires are much exposed and the pipework is completed. Pipes are also being laid north-eastward from Manchester to Leeds, and temporary wires will be provided, to be replaced later on by a permanent cable. It is satisfactory to learn that this work will be completed before the end of the financial year.

Proposed Electrical Post.—Interest in Count Taeggi Piscicelli's proposal to establish a system of electrical post transmission at 250 miles an hour, is revived by the announcement that a syndicate has been formed to put the invention to a practical test in Italy. Only one-third of the total capital of £150,000 is proposed to be raised in this country and the other two-thirds in Italy and France. The avowed object of the syndicate is "to demonstrate the invention on a practical scale," but however interested the public may be in such a scheme, we doubt if their interest will carry them to the length of putting their money into a concern which is admittedly formed to experiment without much prospect of profitable business in the near future. Count Piscicelli's idea is to erect aerial wires along which aluminium boxes containing the mails would be transmitted by electrical propulsion at a speed of something like 250 miles an hour. This main system would be supplemented by local systems serving the towns *en route*, and the invention involves the installation of costly automatic and other apparatus. The initial expenditure on such a system would thus be very great, and it might or might not prove to be of practical advantage. If the syndicate should progress so far as to erect an experimental line, we shall watch the results with the deepest interest. Apparently the inventor was not able to convince the Postmaster-General of the feasibility of his system, as it will be remembered the original proposal was to carry out the first experiments in this country.

German Electrical Depression.—The stagnation under which the electrical industry in Germany has been labouring for the past two years or so forms the subject of a brochure which has been issued by Dr. Bürner, of the

Digitized by Google

Association for Guarding the Interests of German Electrotechnics. This expert estimates that in 1900 there was about £119,000,000 invested in electrical works in Germany, and he attributes the severe crisis which the industry has undergone, and from which it is still suffering, to various causes. First and foremost, he says, the electrical companies, instead of confining their activity to manufacturing, engaged in promoting ventures and obtaining concessions, and in building electric roads, lighting plants, etc., in the towns and rural districts, which should have been left to the municipalities, financial promoters, and private companies. Further, a great mistake was committed in erecting and conducting branch electrical factories in foreign countries, which caused numerous competitors to spring up in those countries, and led other German companies to enter the foreign business, thereby producing a sharp struggle to obtain profitable orders. As a third error, Dr. Bürner names the practice inaugurated by the electrical concerns of establishing installation shops in all the cities and large towns of Germany, instead of leaving that part of the business to the resident plumbers and installation firms. Dr. Bürner does not favour the plan of uniting the German electrical companies in one common concern, but urges the formation of syndicates to regulate and protect prices and limit production where such is profitable. His main recommendation to the industry, however, is to endeavour to extend and increase the export trade.

New Books.—"Fowler's Electrical Engineer's Year-Book and Directory, 1904" (The Scientific Publishing Company, Manchester; 1s. 6d.). The ever-widening field of electrical engineering has been responsible for many amendments and additions that have been made in this popular little handbook. For instance, the revised general rules for wiring issued by the Institution appear in this edition, and some valuable tables of data have been interpolated with a view to enriching the text, which in many parts has been largely rewritten, as, for example, in the case of the sections on measuring instruments, electric distribution, meters, and dynamos; while some interesting new matter on polyphase transmission and induction motors has been included. A valuable feature of the book is the data relating to station plant, equipment, and staff which are given of over 500 installations in the country.—"Transactions of the American Electro-Chemical Society" (The American Electro-Chemical Society, Philadelphia), vol. iv. A large number of valuable papers are reprinted in this issue, together in some cases with the discussions at the meetings at which they were presented. Among the papers we notice the following: "Note on Some Theoretical Considerations in the Construction of Resistance Furnaces," by Mr. FitzGerald; "Advances in Electro-Metallurgy of Iron Production," by Mr. Ruthenberg; "A New Type of Electrolytic Cell," by Mr. Salom; "The Electrolysis of Water," by Messrs. Richards and Laudis; and "The Thermo-Chemistry of the Theory of Electrolytic Dissociation," by Mr. Richards.—"Electric Traction," by Mr. J. H. Rider. (Messrs. Whittaker and Co.; 10s. 6d.). This book, to which we referred last week, has now been published. It is described as a practical handbook on the application of electricity as a locomotive power. We hope to notice the work more extensively in a subsequent issue.—"The 'Daily Mail' Year Book for 1904," edited by Mr. Percy L. Parker (The Amalgamated Press, Limited, London; 1s. 6d.).

Electricity for Rangoon.—The introduction of electricity in Indian cities has led to much local controversy and adverse criticism of the methods employed by municipal authorities in that portion of the Empire. Just now there is a stiff fight proceeding over the tendering for the electric lighting and tramway concession in the city of Rangoon, and our contemporary, the *Indian and Eastern Engineer*, throws an interesting light on the way the city authorities are going about the scheme. From our contemporary's remarks, it would seem as if the one object the municipality has in view is to put as many restrictions as possible on the concessionaires in carrying out the work. Thus, the tenderers have been forced to agree to pay a minimum tramway track rent of Rs 3,000 per mile of double and Rs.2,000 per mile of single track per annum, which is held to be an excessive amount when compared with other Indian cities. For instance, in Calcutta, where there is a greater track mileage, much greater scope for expansion, and a traffic far superior to any that can be hoped for in Rangoon, the total track rent is only Rs.30,000 per annum, whereas in the present case, the total rent, based on the above figures would amount to Rs.36,000. The electric tramway in Colombo pays only Rs.800 per annum per mile of track up to eight miles, and above that Rs.500 per mile. The greatest trouble, however, appears to be in the matter of tenders. Our contemporary states that a Calcutta firm should have been awarded the concession on the original tenders, but fresh tenders were called for on the plea that no proper comparison could be made of the four tenders which were received. If anyone is to blame for this, it is held to be the municipality itself, since the tenders were based on its own tender form. The one satisfactory feature about the whole scheme would seem to be in regard to the plans for lighting the city. These are admitted to be generous and well conceived, although some exception might perhaps be taken to the method of installation, which leaves little provision for future extensions.

Mechanical Stokers.—At the meeting of the Society of Engineers held on Nov. 30, Mr. Albert Gay, the electrical engineer of Islington, read a paper on the use of mechanical stokers in electricity generating stations. The paper is commenced with a table which gives approximately the detailed losses in British thermal units from the coal fed into the boiler down to the electricity delivered to the lamps in consumers' premises. These approximate figures show that only 7·27 per cent. of the British thermal units in good coal are actually developed in the lamps. The largest losses are in the gases passed up the chimney and in the engine exhaust. Mr. Gay, like a number of other writers on the subject, takes the absolute efficiency of the engine into his calculations instead of the practical efficiency. In other words, he compares his steam-engine with a heat engine able to work down to absolute zero. A description is given of a large number of mechanical stokers, and then follow figures of tests. The first table of these deals with the underfeed stoker which has been experimented with at the Islington station. The comparisons between this and hand firing are not so valuable as they would otherwise be, because during the trial of the mechanical stoker the boiler was not forced in any way. In fact, the output in steam from the hand-fired boiler in nine hours was approximately the same as that from the mechanically-stoked boiler in 16 hours. The author concludes that the average evaporation with mechanical stokers is somewhere between 9lb. and 10lb. of water per pound of coal. He, however, gives records where these figures were considerably exceeded. Perhaps the most interesting part of the paper is the end, in which replies received from a large number of central stations in London on the question of mechanical stoking are given. The conclusion from these is that in London it pays to use the best coal, and in several cases hand firing has been found more economical and less liable because of smoke trouble than mechanical stoking. As the author puts it, a large

Digitized by Google

proportion of the cost of fuel in London is made up of carriage, and hence it pays to carry a high-class fuel rather than a low-grade coal.

Electric Transmitting Mechanism for Automobiles.—In many forms of automobiles a considerable disadvantage is the use of the intermediate gearing which is necessary to transmit the movement from the motor in front of the car to the differential, which is generally placed on the rear axle. To give the different changes of speed a number of sets of gears is necessary, thus involving much loss of energy in the transmission, as well as increasing the mechanical shocks of the car. A device which is designed to overcome this disadvantage, and give an easy running, has been recently brought out in Paris, and is stated to have worked very successfully. The transmission is carried out by an electric device, which will be understood from the following abstract of an article illustrating the invention, published in the *Western Electrician*. The shaft of the petrol motor has its flywheel formed by the field magnets of a dynamo. The armature of this dynamo is fixed on a shaft carried in bearings which passes to the rear. A second dynamo has its field fixed and independent, while its armature is carried on the main shaft. To the end of the shaft is fixed the bevel gear, which engages with one or the other of the bevel gears of the differential which is mounted on the rear axle of the car. The two machines are coupled together and excited in series, the field of the second machine being shunted by a rheostat of 12 points. When the rheostat is short-circuited the first machine acts as a simple coupler, and a very small slip between its field armature suffices to obtain the current which corresponds to the normal couple of the petrol motor. This position represents the maximum speed of the car. If the resistance of the rheostat is increased, the field current is increased in the second machine. The counter E.M.F. which is thus given makes it necessary, for an equal current, to obtain a greater slip in the first machine. The speed of the car therefore diminishes and the effort increases, since to the normal couple of the petrol motor is added the couple of the second machine, the latter being proportional to the field strength, and can, therefore, be varied as desired by the action of the rheostat, which acts thus as a speed controller. Another set of connections gives an electric braking action by reversing the rate of the two machines. The speed reversal, however, cannot be obtained electrically, but is brought about mechanically by shifting the bevel gear to one side or the other of the differential. In general, the principle of the above arrangement is similar to that used on the single motor carriages on the North-Western Railway.

Fog and Electricity.—Following up his lecture before the Physical Society in London, Sir Oliver Lodge has explained to the members of the Scientific Society of the Birmingham and Midland Institute his suggestions for the dispersal of fog by means of electricity. He showed that an alternating current would not give the effect required in order that the particles of fog might cohere, but that an unidirectional discharge was wanted. On the other hand, alternating current had the advantage that exceedingly high potentials could be obtained. He, therefore, suggested that while alternating currents might be generated for the purpose, a mercury interrupter could afterwards be used in order to damp down the oscillations in one direction. The Cooper-Hewitt lamp evidently prompted the idea, and it will be interesting to see how far experiments on the lines laid down by Sir Oliver Lodge will be successful on a large scale. He has this week added to his previous information on the subject in a letter addressed to Mr. J. W. Bradley, M.I.Mech.E., who had written suggesting that it might be possible to devise an arrangement to be fitted to street arc lamps so that electricity could be discharged at a large number of points and in situations likely to be productive of most benefit. Sir Oliver commends the suggestion as practical, and proceeds: "The difficulty is the insulation. If that could be guaranteed, the matter would be comparatively easy; but the potential is extremely high, say 100,000 volts. The quantity is next to nothing and very little power is sufficient if only one could avoid leakage." Describing the Liverpool experiment, he says: "I was using a potential higher than 100,000 volts; one could take sparks 4in. long. But a good deal smaller voltage would do if there are walls or other earthed surfaces in the neighbourhood. For a lofty isolated mast the potential must be higher in order to secure adequate discharge. My view, of course, is that a town fog ought not to be produced; that it is very extravagant of a community to go to the double expense, first of producing a fog by incomplete combustion, and next of coping with it. But inasmuch as combustion reform will take some time, and meanwhile fogs are a nuisance, it is quite possible that something temporary ought to be done even in a town. Fogs at sea and at harbours come in a different category, and it is quite appropriate to attempt to deal with them. There is, however, no more difficulty in dealing with one than with another, and, in fact, the thicker the fog the more easily it is to deal with, if only adequate arrangements are made for the genuine supply of electricity into the air."

The Carbon Vaporised in Incandescent Lamps. Incandescent lamp filaments, as is known, are mostly of amorphous carbon as obtained by calcination of a vegetable thread. This, on being brought to a white heat in the vacuum by the electric current, will yield a trace of carbon vapour, the condensation of which on the walls of the bulb in most cases results in the latter becoming lined with a brown coating, producing a gradual darkening of the lamp. In a paper read before the French Academy of Sciences Prof. Berthelot examines the state of this vaporised carbon at the lowest possible temperatures, comparing it with the well-known allotropic modifications of carbon—namely, diamond, graphite, amorphous carbon. The main results of this investigation are as follows: Carbon exhibits an appreciable vapour tension at a temperature not exceeding 1,500deg. C., this tension being so low as to require several hundreds of hours to produce some milligrammes of condensed carbon even in the nearly absolute vacuum of electric lamps. On the other hand, the carbon thus vaporised at the lowest possible temperatures is, under Prof. Berthelot's experimental conditions, amorphous carbon without any addition of graphite or diamond. The temperature at which a vapour tension of carbon may be noted proves thus about 2,000deg. below the boiling temperature, which, according to Prof. Violle, is 3,600deg. This interval is very much larger than the interval of temperatures, during which most of the remaining bodies exhibit an appreciable vapour tension. This tension, however, in the case of carbon, does not, in Berthelot's opinion, correspond with a simple vaporisation occurring without any intimate change in the chemical constitution of the body in question. Although representing the same chemical element, carbon assumes in the solid state a multitude of different conditions exhibiting rather different physical and chemical properties. There seems to be a series of progressive condensation, the limits of which would correspond to the different modifications of carbon. According to ordinary analogies, the physical properties of compound bodies susceptible of being formed directly are related to those of their components,

Digitized by Google

but they are more or less modified on account of the energy loss undergone in virtue of this direct combination. The combination of hydrogen, boiling at −252deg., and that of oxygen, boiling at −182deg. C., will thus give water, which boils at +100deg. The internal force maintaining at the gaseous state the free molecules of hydrogen and oxygen has thus decreased to an enormous extent, as corresponding with the 59,000 calories lost at the instant of their combination with the formation of a molecule of gaseous water. The same seems to be true of carbon in its combinations with hydrogen. The real existence of this element in a true gaseous state, no matter what the origin, is shown by spectral analysis, both in the electric arc and in the sparks, through its oxides, hydrides, etc., as well as in the flames produced by the combustion of these different compounds.

Recent Developments in Gas-Engines.—The members of the Junior Institution of Engineers held a meeting at the Westminster Palace Hotel, on Friday, to hear a paper read by Prof. D. S. Capper on "Recent Developments in the Construction and Working of Gas-Engines." After a short reference to the Otto gas-engine, the author showed that the efforts of experimenters have been chiefly directed either to the improvement of the Otto cycle, or to endeavouring to replace the Otto cycle by one which shall give greater efficiency and easier regulation. A third direction in which developments have been made is the cheapening of fuel by the introduction of producer gas and use of blast-furnace gas. The author then described the modifications in the Otto cycle engine introduced by various makers, resulting in the consumption of coal gas being reduced, the inequality of the crank effort being partly overcome and the speed being kept constant to about 1 per cent. by automatic governing. Probably the largest engines on the Otto cycle hitherto constructed have been made by the Société Cockerill, of Seraing. Engines with two tandem cylinders, 51in. in diameter, have been made by this firm and develop 2,500 i.h.p. Among earlier attempts to replace the Otto engine was that made by Mr. Dugald Clerk, who removed the suction and compression strokes to a separate pump cylinder. Although this engine did not supersede the Otto, it has been reintroduced, with modifications, as a double-acting engine by Messrs. Korting, and is now being manufactured in sizes up to 1,000 h.p. and over. Another departure from the Otto principle is the engine made by the Diesel Company, which closely follows the Carnot cycle, and if this can be successfully applied to gas-engines of large size, constant pressure ignition in a gas-engine will be an accomplished fact. The engine recently invented by Messrs. Vogt and Hecklinghausen was designed to overcome the difficulty of cooling with the thicker castings rendered necessary by the increased explosion pressures, and promises to give striking results. By recent improvements in construction the gas-engine has been brought to a position in which in economy it surpasses the steam-engine, and in regularity of running, steadiness, size, and handiness for given power it approaches very closely and promises to surpass the steam-engine also. Compound gas-engines have been tried by Messrs. Crossley and by other makers, but although these have been successfully worked, the gain has not been commensurate with the added cost, and they have therefore not been adopted as a commercially possible type. If the reciprocating engine were to give place to a rotary turbine there is little doubt that its future would bid fair to equal, and probably to surpass, the steam-engine for universal application. Many experimenters are working on the problem of a gas-turbine, and it is rumoured that a solution has been found. The place the reciprocating gas-engine has already won is proved by the significant fact that even firms which have created the demand and met the supply for high-speed steam electric generators are almost without exception experimenting with gas-engines, as the coming thing which will supply the second, if not the first, string to their bow. The meeting closed with the announcement of a visit on Dec. 19 to the electricity works of the Walthamstow Urban District Council, which are operated by gas-engines.

Electrical Development in Cornwall.—We briefly referred last week to an electric tramway line which has been laid down in one of the mining districts of Cornwall for the carriage of iron ore, and we are now able to give some interesting particulars of the system, which is probably the first of its kind in this country. It has been carried out in connection with the recently constructed Camborne and Redruth electric tramway, and the Urban Electric Supply Company have contracted to carry all the ore from East Pool and Wheal Agar to the stamps at Tolvaddon, the distance being about 1½ miles. An average traffic of about 200 tons of ore a day has been provided for. The ore is first carried from the mines over about half a mile of the Camborne and Redruth tramway permanent way, branching off at the power station at Carn Brea. A light railway has been laid down on private property, crossing two main roads to the stamps. In the construction of this line it was necessary to build a bridge over the gasworks road, and a large amount of levelling had to be done; a trestle bridge was also found necessary from the second to the third stamps, owing to the difficulty of getting curves of a reasonable radius in such a cramped area. This special work in conjunction with the permanent way produced many difficulties for shunting of trucks and locomotives owing to the limited space at disposal. Locomotives are used for drawing the freight cars. They were supplied by Messrs. Milnes and Co., and the electrical equipment, including the motors and controllers, by the British Thomson-Houston Company. Each locomotive is equipped with two 25-h.p. motors of the firm's K-60 type. The rolling stock consists of 14 side-tipping steel trucks—eight carrying 2¼ tons per truck, and six three tons per truck. These trucks are provided with powerful brakes on all four wheels, and a train will consist of three trucks and locomotive. The construction of the line, etc., was carried out for Messrs. Edmundson's Electricity Corporation, Limited, by the resident engineer and manager, Mr. F. S. Hanning. Incidentally we are able to give particulars of the works, which have been completed under the Camborne, Redruth, and Illogan lighting orders and the Camborne and Redruth tramway order. The entire installation of both the lighting and tramway system was carried out direct without contractors, with the exception of Messrs. Callender's Cable and Construction Company, who laid the cables to the instructions of the resident engineer, and of which over 100 miles have been put down in mains and network. The present position of the undertaking may be stated thus: the equivalent number of 8-c.p. lamps connected is 6,000; number of motors, 17, representing about 200 b.h.p.; number of tramway motors, 10, equal to 500 b.h.p., making the grand total equivalent to 25,000 8-c.p. lamps. Such a result for 12 months' working may well be considered as excellent when compared with some of the large industrial towns in the kingdom. For instance, Rochdale, with a similar combined system, with a population of 83,000, has only an equivalent of 18,000 8-c.p. lamps after three years' working. We understand that the company have arranged with the Post Office to have letter-boxes affixed to the cars, the mails to be collected hourly at both Camborne and Redruth, thus imitating the example set by some of the northern towns.

WORKS' VISITS.

II.—Messrs. Royce, Limited, Trafford Park, Manchester, Works.

As was the case in the first article of this series, we have here to deal with extension works erected at a distance from the original site. Messrs. Royce, Limited, established their head works at Hulme, Manchester, in 1884, and soon gained a local reputation for their dynamos and motors. But from local circles the good repute of the firm's manufactures has now spread even to the Colonies. Perhaps it is with electric cranes and hoists that the name of "Royce" is more generally associated. Indeed, the firm claim to be pioneers in the particular branch of electrical and mechanical engineering dealing with the application of electrical energy to cranes, hoists, etc., and have specialised in this department with a degree of success which may be justly described as phenomenal. From a small beginning the establishment at Hulme increased until it occupied the full extent of the land available, and then recourse was had to a site which offers greater facilities. This site is situated in Trafford Park, Manchester, directly opposite Messrs. Glover's cable works. It is three acres in area, and by virtue of position enjoys all the advantages due to the elaborate system of railways designed to serve the several works on the Trafford Park Estate, besides those advantages incidental to the supply of power at the cheap rate of 1¼d. per unit provided by the Estate Company, and to its close proximity both to the Manchester Ship Canal docks and the Bridgewater Canal.

Main Bay of Machine Shop, looking towards Side Bays, Messrs. Royce Limited, Trafford Park Works.

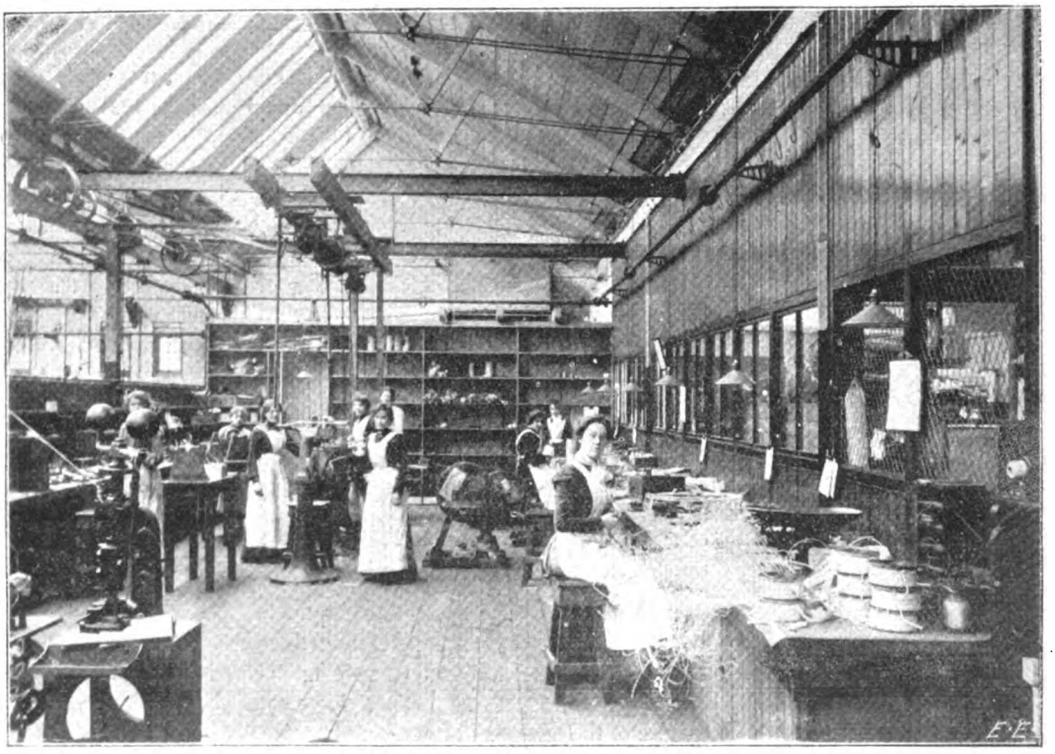

FIG. 2.—Girls' Bay, Trafford Park Works.

It is the principal object of this article to describe the

Digitized by Google

branch works which Messrs. Royce, Limited, have erected upon this site. In regard to what may be looked upon as the first instalment of these works the firm would not seem to have erred on the side of excess, but rather to have adopted a policy of moderation, while at the same time making ample provision for future developments. In the normal course of things this branch will at some date not far distant exceed the present head establishment in size and importance. Indeed, from the electrical point of view, it may be said to already surpass the older establishment in the latter respect, since the bulk of the electrical work formerly carried on at Hulme has been transferred to the branch, the Hulme establishment now confining its attention more to structural parts for cranes, and to the manufacture of controllers, arc lamps, and the various small electrical accessories specialised by Messrs. Royce.

Roughly speaking, the new works consist of two buildings—one containing the machine shop, with auxiliary bays, stores, offices, etc., and the other being a foundry. The main bay of the machine shop—a view of which is shown in Fig. 1—measures 160ft. long by 40ft. span. It is here where the various operations, including heavy machining, fitting, erecting, and testing incidental to the manufacture of the firm's standard type dynamos and motors, are done. To the right of this bay and at right angles to the same are ranged six other bays, each having a floor area of 60ft. by 18ft. 3in. The first of these smaller bays (Fig. 2) may be termed the girls' bay, for here woman labour is employed in winding light magnet coils on metal bobbins, and in making cotton-covered wire adapt itself to the shape of formers in its process of evolution towards the finished armature coil state. In the

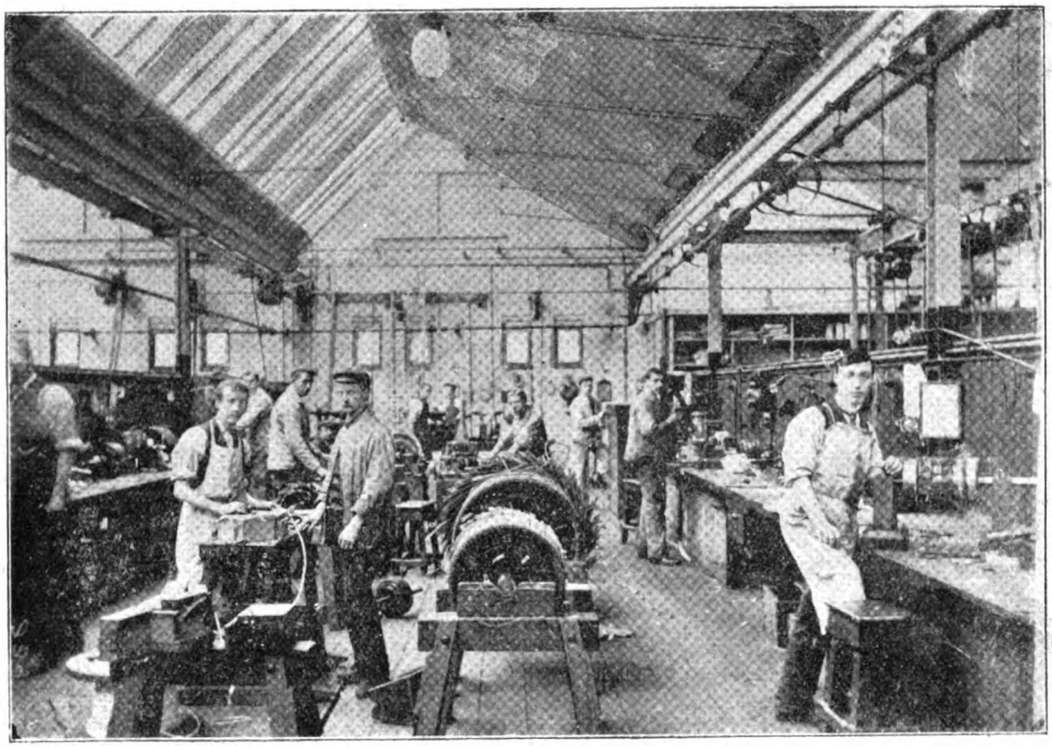

FIG. 3.—Armature-Winding Bay, Trafford Park Works.

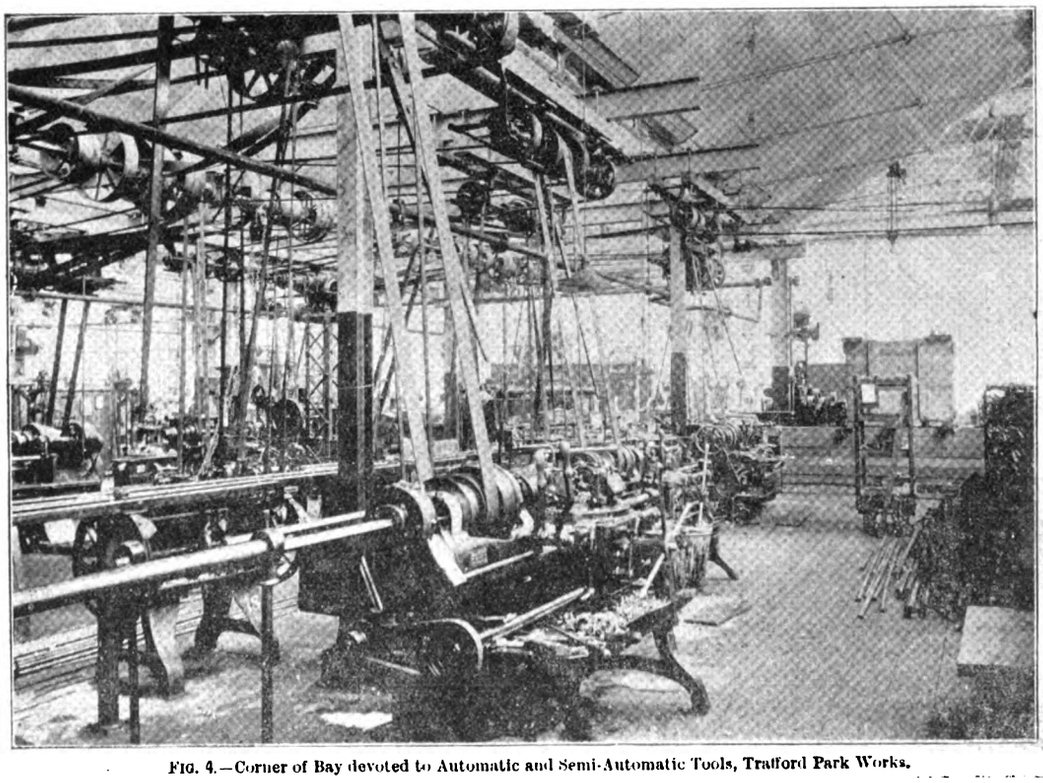

FIG. 4.—Corner of Bay devoted to Automatic and Semi-Automatic Tools, Trafford Park Works.

Digitized by Google

same department the smaller sizes of armatures are wound, the girl operatives being particularly adept at this class of work. The next bay (Fig. 3) is devoted to the winding

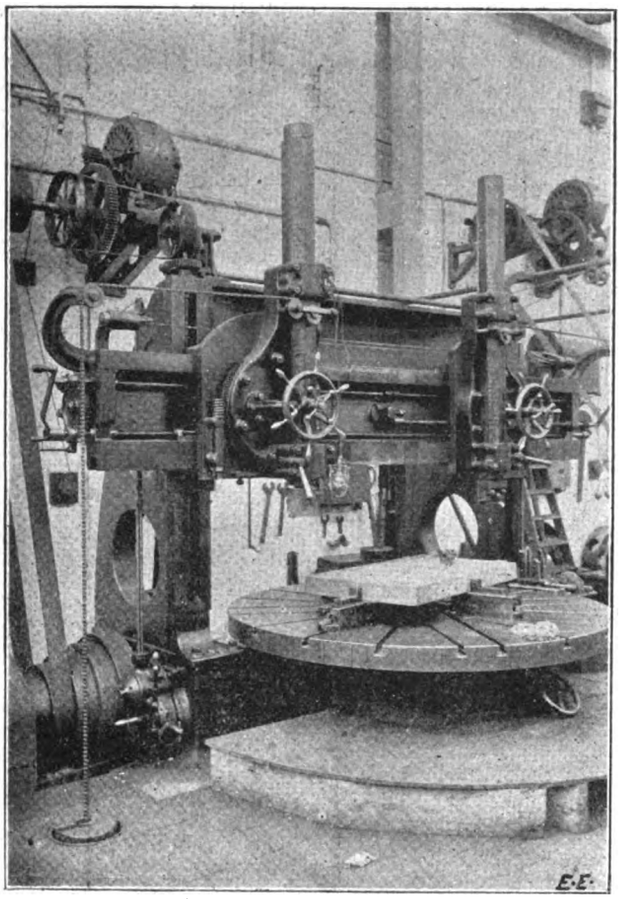

FIG. 5.—View of 72 Boring Mill, showing Electrical Drive, Trafford Park Works.

of the heavier armatures and field coils, requiring man labour, and abutting on this is a bay in which small machines are erected, commutators built up, and light fittings constructed. The fourth bay in the order of succession here observed is equipped with medium weight turning lathes, drills, and heavy semi-automatic tools, while the fifth bay has been set apart for the milling of armature cores, general milling work, and hack saws, etc. The sixth and last bay of this range—a corner of which is shown in Fig. 4—contains automatic and semi-automatic machines of divers descriptions and sizes for the manufacture in bulk of small duplicate parts, such as screws and bolts, and the turning of armature shafts, etc. The offices are located in the front of the building, the stores adjoining the girls' bay, while the foundry is a detached building situated in the rear of the machine shop. Of the buildings themselves there is little to be said, except that iron enters largely into their construction instead of heavy masonry. A notable example of this is seen in the main machine bay, a feature of which is the independent support given to the powerful overhead travelling crane which serves it. The excellent lighting of the shops by day also impressed us. But it is principally in the direction of equipment that our interest gravitates when new works come under review. In the present case we were prepossessed of the knowledge that Messrs. Royce had long specialised in the application of electrical drives to machine tools—hence journeyed to Trafford Park with expectations high. Nor were we, in fact, disappointed, but, on the contrary, found works set out to illustrate the advantages peculiar to the electric motor for driving machinery of all classes used in the engineering trades. Several of the drives employed call for something more than passing notice. To this category belongs that applied to the planing machine, shown on the left in Fig. 1. This machine is capable of taking work 4ft. by 4ft. by 16ft., and is electrically driven by means of a motor fixed on the wall face and coupled up to a short length of shaft, which in turn carries the necessary driving pulley and flywheel. The length of drive allowed varies, of course, with the nature of the work and with the power to be transmitted. In this particular case the length is necessarily considerable. Another interesting drive is applied to the 72in. boring mill shown in Fig. 5. The motor, it will be observed, is carried from the wall on a bracket support, and has mounted on its shaft a rawhide pinion, which gears into a spur wheel mounted on the same shaft as the cone driving pulleys. In conjunction with this motor is used an automatic reversing switch, which allows the mill to be run in either direction. This switch is controlled by means of two ropes,

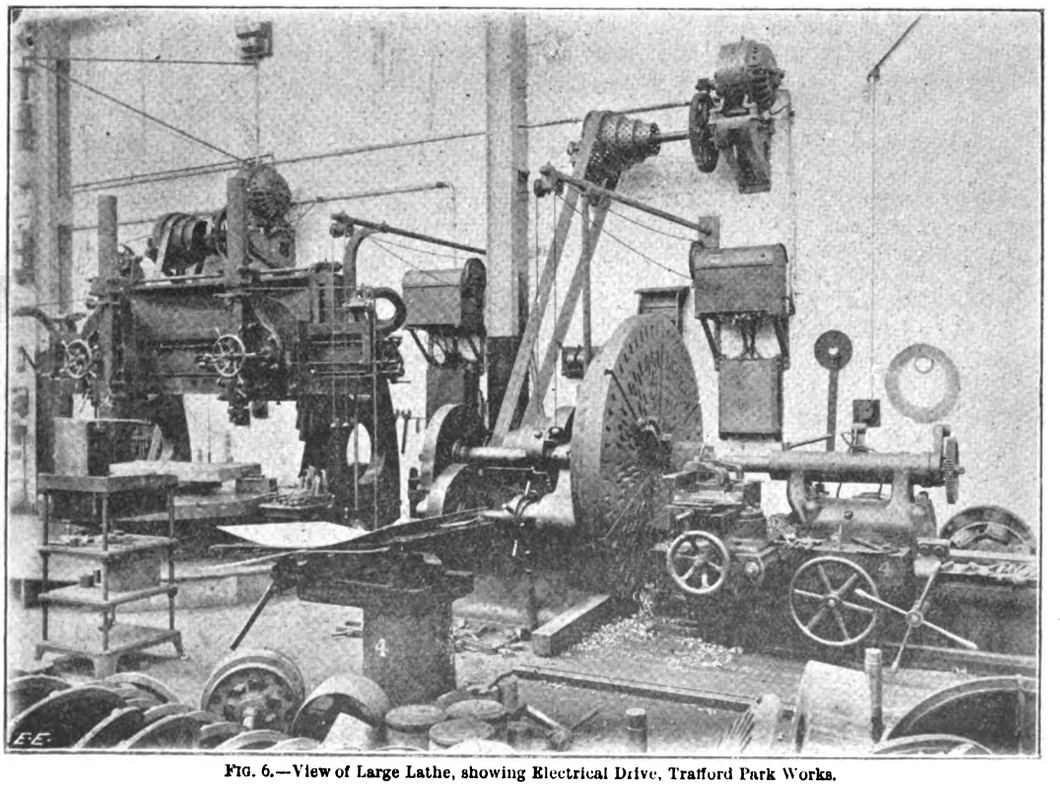

FIG. 6.—View of Large Lathe, showing Electrical Drive, Trafford Park Works.

which are brought from the switch over grooved pulleys to the side of the man operating the machine. If needed, these controlling ropes can be carried along the machine so that the operator can start, stop, or reverse the motor

Digitized by Google

driving his machine tool from any point on the machine. Similarly driven and controlled is the large lathe shown in Fig. 6. The special arrangement of the controlling gear is seen to better advantage in this illustration. Another and perhaps a greater novelty in the way of drives is that illustrated in Fig. 7. This drive is transmitted from a motor carried at the top of a latticed girder mast to a hack saw below, the driving shaft being geared to the motor, and fixed underneath the same as shown. Numerous other special drives are included. Indeed, the works might almost be regarded as an exhibition in this respect—a circumstance which does but emphasise the fact that the application of electrical drives has been constituted a special study by Messrs. Royce. The main bay of the machine shop is served by a "Royce" three-motor overhead travelling crane, having a lifting capacity of 10 tons, while side bays 2, 3, and 4 are each provided with an overhead hand-driven travelling crane capable of lifting one ton, communicating with a narrow-gauge railway which extends from end to end of the works.

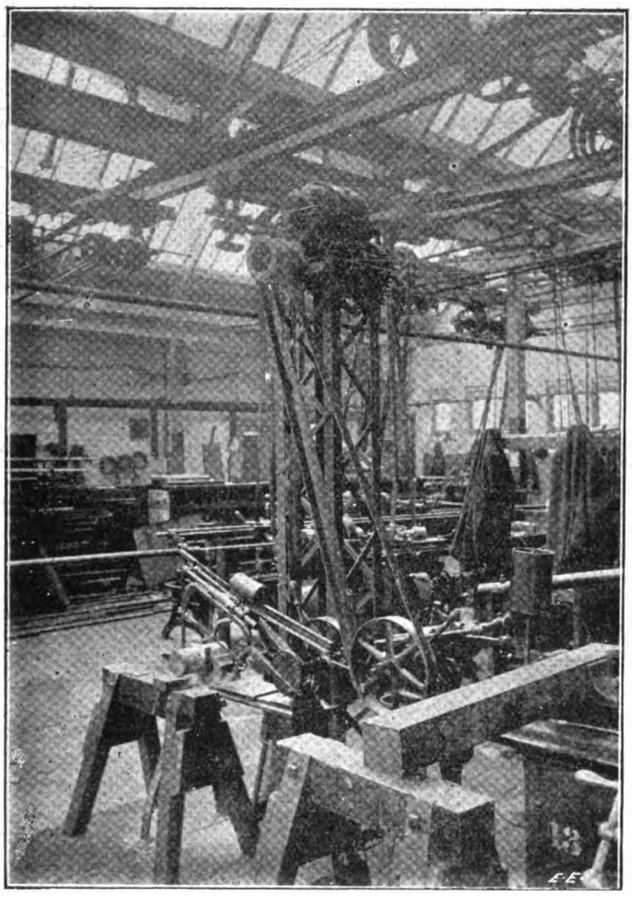

FIG. 7.—View f Motor mounted on Iron Mast, Trafford Park Works.

Most of the automatic tools comprised in the equipment of the works are by Messrs. Alfred Herbert, Limited, Coventry, a noteworthy exception being in the case of the smaller automatic tools, which were designed and made by Messrs. Royce themselves. The method observed in the arrangement of the machine tools generally is such as to facilitate the evolution of the different parts used in the construction of the firm's manufactures from their embryo to their finished state. In other words, the amount of handling required during the progression of the different parts towards the stores or erecting branch, and so on to the testing and packing departments, is reduced to a minimum.

But before proceeding with the question of the works organisation a little further reference may be made to the foundry. This is conveniently placed in the rear of the machine shop, from which it is, however, quite detached. It is contained within a building measuring 80ft. by 40ft., and has been designed for an output of about four tons of castings per day. The equipment includes a Royce three-motor overhead travelling crane having a lifting capacity of 10 tons. The cupola which serves the foundry with its requirements of molten metal is provided with a blower driven by an electric motor. This motor is connected to a switch combining a variable-speed arrangement, whereby any desired blast can be obtained. An electric hoist, which incidentally serves to illustrate another of Messrs. Royce's specialities, is used to raise the iron and other materials required to feed the cupola. Contrary to the practice of many dynamo builders, Messrs. Royce make all the iron castings used in the machines which they turn out.

These works have been designed and equipped for the manufacture to stock of all the parts used in the construction of the firm's standard sizes of open, ventilated, and enclosed types of dynamos and motors on the most economical lines. It may be explained here that their standard four and six pole enclosed and ventilated type machines range in output up to 75 b.h.p. as motors and to 50 kw. as generators. For larger outputs, open-type machines with six or more poles are supplied. As a general rule, machines of the sizes mostly in demand, ranging from

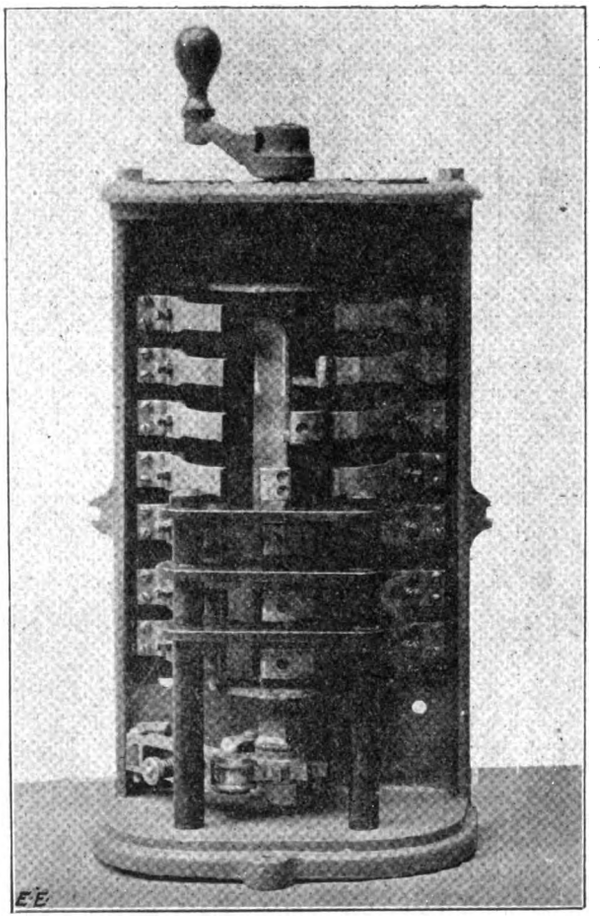

FIG. 8.—Tramway Type Controller for Crane Work, Trafford Park Works.

3 b.h.p. to 40 b.h.p., can be supplied in a finished state from stock, but in regard to the larger sizes the constituent parts only are made to stock, these being drawn upon as required to execute orders. The great feature, then, of the works organisation consists in that the machine shop is steadily employed in making finished parts to stock. This applies not only to small parts, but also to large ones, such as armature and field-magnet cores, frames, shafts, bed-plates, etc. When it becomes necessary to replenish the stocks for any standard size of machine, the necessary parts of this are each repeated in series of 20's. The jig and template system being employed throughout, it is ensured that like parts of any series are absolutely identical, and therefore interchangeable. If a modification in design or a new pattern of machine is to be introduced, it is commenced with a new series—never in the middle of one. The works had not been started many months when we visited them and took the accompanying photographs, but even then parts were in stock, we understood, for about 200 machines of the different standard sizes supplied. To illustrate the promptitude which the above organisation ensures in the execution of orders, it may be

Digitized by Google

mentioned that one order for 18 motors of different sizes for one month's delivery was going through the shops with every prospect of being completed within the time specified. A few words may be added here with regard to the testing equipment provided. This is located at the erecting end of the machine shop (main bay) adjoining the stores, and includes motor-driven generators designed to furnish almost any pressure between 65 volts and 500 volts. For the higher pressures required for breakdown tests an additional set is being installed. This set will be capable of supplying pressures from three to five times greater than the working potentials of the machines to be tested.

It will not be out of place to deal now briefly with the features which distinguish the finished machines turned out from the above described works. In this connection it is noteworthy that Messrs. Royce's standard type machines for continuous running are designed to admit of them giving their respective outputs for periods of six hours with a temperature rise not exceeding about 70deg. F., and to render them capable of carrying a 10 per cent. overload for two hours, or an overload of 25 per cent. for periods not exceeding 15 minutes. The machines are of simple but substantial construction, all parts being easily accessible. In all the smaller sizes the yoke rings are made of high permeability steel, with magnet limbs of mild steel bolted in. The construction admits of a field coil being removed, if necessary, without disturbing the armature, this being of great advantage in cases where the machines are not provided with split yokes. All machines, however, above 30 h.p. are provided with split yokes. The armatures are of the solid drum type, having cores built up of plates possessing high magnetic permeability and low hysteresis, insulated from one another in such a manner as to reduce the eddy currents in a complete core to an exceedingly low value. Each core is mounted on a substantial hub, which is designed to carry the commutator, and is so arranged that the shaft can be removed at any time without disturbing the winding or the commutator. In the case of generators this method of construction allows of the armature being keyed directly on to the engine crank-shaft. The coils composing the armature winding are arranged symmetrically, thereby ensuring equal self-induction and equal position of commutation, while all the coils being former-wound, a few spares can be kept for eventual repairs.

As regards the commutators, these are built up of hard-drawn copper segments, each section being insulated from the next and from the sleeve by means of mica. The commutator bars are held in position at each end by special rings having a V section, and the whole is put together under hydraulic pressure and held by means of stout bolts. The brush gear is so designed as to allow of easy accessibility, and the brushes are of high-grade carbon. In machines of the smaller sizes the brush-holder supports are carried from a rocker bar mounted on the bearings, but in the standard 50-kw. machine and larger sizes they are carried from the yoke, which enables the whole of the brush gear to be held with much less vibration. Moreover, the insulation can be carried out in a more substantial manner. Field coils are usually wound on heavy metal bobbins, which can be removed from the magnet cores. The bobbins are very thoroughly insulated, and the inside ends of shunt coils are each connected to an insulated flexible conductor, which is so arranged that, should the end connection be broken, it can be repaired without rewinding the coil. Each coil is impregnated *in vacuo*, whereby the insulation is rendered practically perfect and watertight. In compound-wound machines the series coils are usually wound with substantial copper tapes, quite separate from the shunt coils. The field magnets are of circular cross-section, which form gives the greatest efficiency for a given length of conductor.

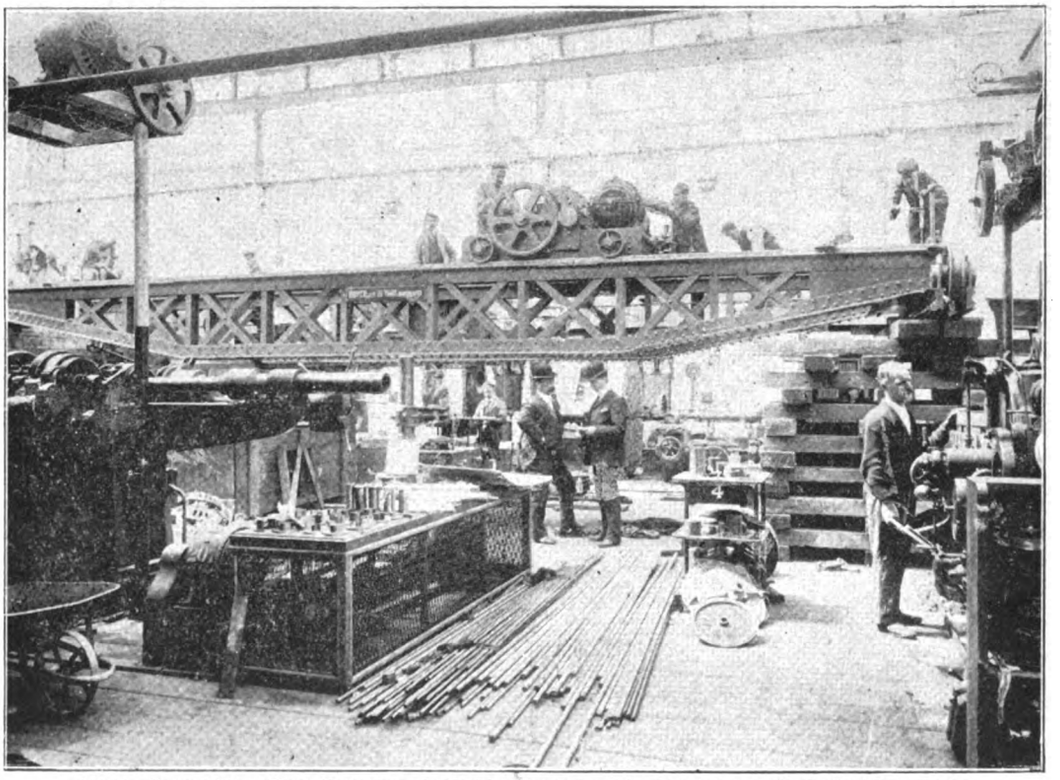

FIG. 9.—View of 10-ton Three-Motor Crane in Machine Shop prior to its shipment to India, Trafford Park Works.

It now remains to describe some of the features embodied in the design of "Royce" electric cranes, which have contributed to the firm's success in this department. In their three-motor overhead travelling cranes the motors employed are almost invariably of the series-wound type, and will consequently run at a constant speed with a constant load, but with a light load will accelerate in a certain ratio. Needless almost to say, these motors are of a design which has been evolved to meet the conditions peculiar to crane work, the result being a type of machine which combines high electrical efficiency with mechanical strength, and is capable of withstanding an overload of 50 per cent. for short periods without distress. They are so constructed as to be totally enclosed and dust-proof. The bearings are of the firm's patent self-oiling type, the bushes of which are arranged to swivel at the centre of their length. Of the three motors comprising the equipment of one of these cranes, that used for actuating the hoisting and lowering gear is of the "Royce" standard slow-speed multipolar type, and is securely fixed in a readily accessible position on the framework of

Digitized by Google

the crab. A noteworthy feature relating to the gearing through which the power developed by this motor is transmitted is the introduction of a patent automatic governor lowering gear, which can be so adjusted as to take charge of all loads when being lowered and control the speeds to within reasonable limits. The cross traversing arrangement which forms part of the crab consists of a motor of similar construction to the hoisting motor, together with the necessary gearing for actuating one of the axles.

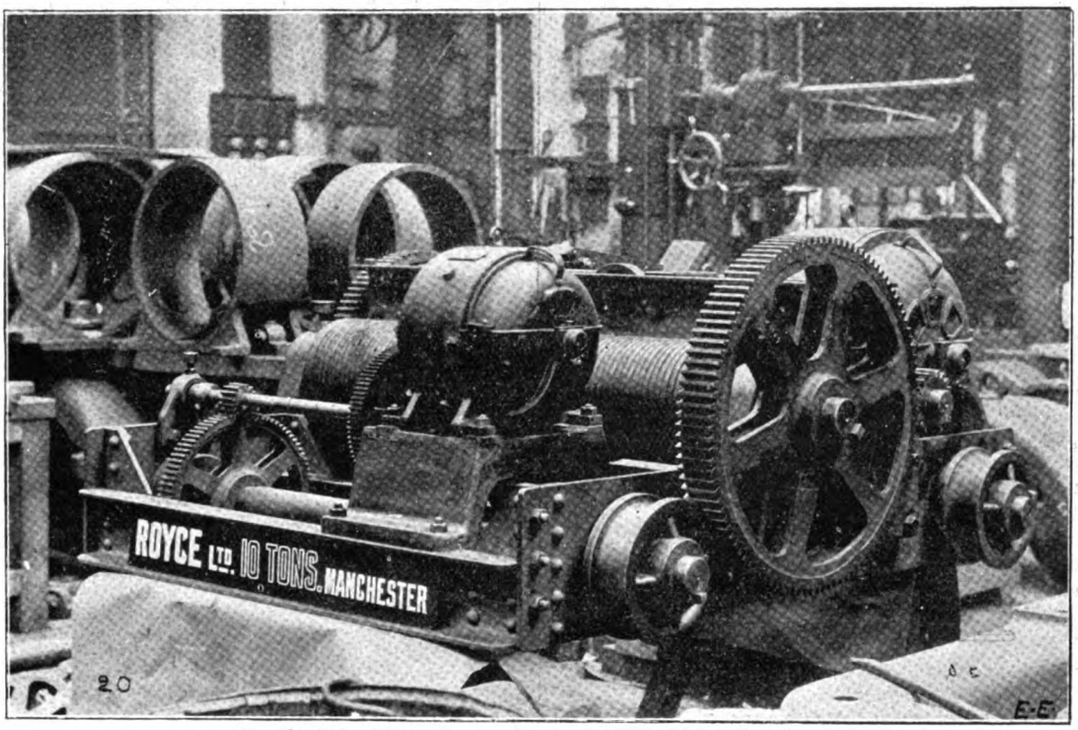

FIG. 10.—Crab of 10 ton Three-Motor Crane for India, Trafford Park Works.

Messrs. Royce obviate the difficulty incidental to the longitudinal travelling of cranes by driving the cross-shaft from the centre of the crane span, thereby ensuring an equal turning movement at each end. Extra expense is incurred by this arrangement on account of the additional wiring necessary, and the special brackets required to carry the motor; but the user gains from the fact that wear and tear of the track wheels and the liability to mount the rails, are reduced to a minimum.

In a crane having a span of, say, 30ft. or more, considerable inertia has to be overcome before the crane can commence travelling, and when it has attained full speed a corresponding amount of energy must be absorbed before it can be stopped. It follows that to start, attain full speed, and stop in the shortest space, must be an advantage worth having from a time-saving point of view. To effect this combination, Messrs. Royce have introduced their patent slipper drive between the longitudinal motor and cross-shaft, which enables the crane driver on starting to give full-speed current without risking damage to his motor. For stopping he can actually reverse the running of his motor. In other words, this drive prevents the longitudinal motor being overloaded in attempting to start a heavy crane too quickly, and permits of it being reversed and used as a brake. The electrical equipment of a three-motor crane also includes three controllers. These are of the tramway type illustrated in Fig. 8. Should the supply

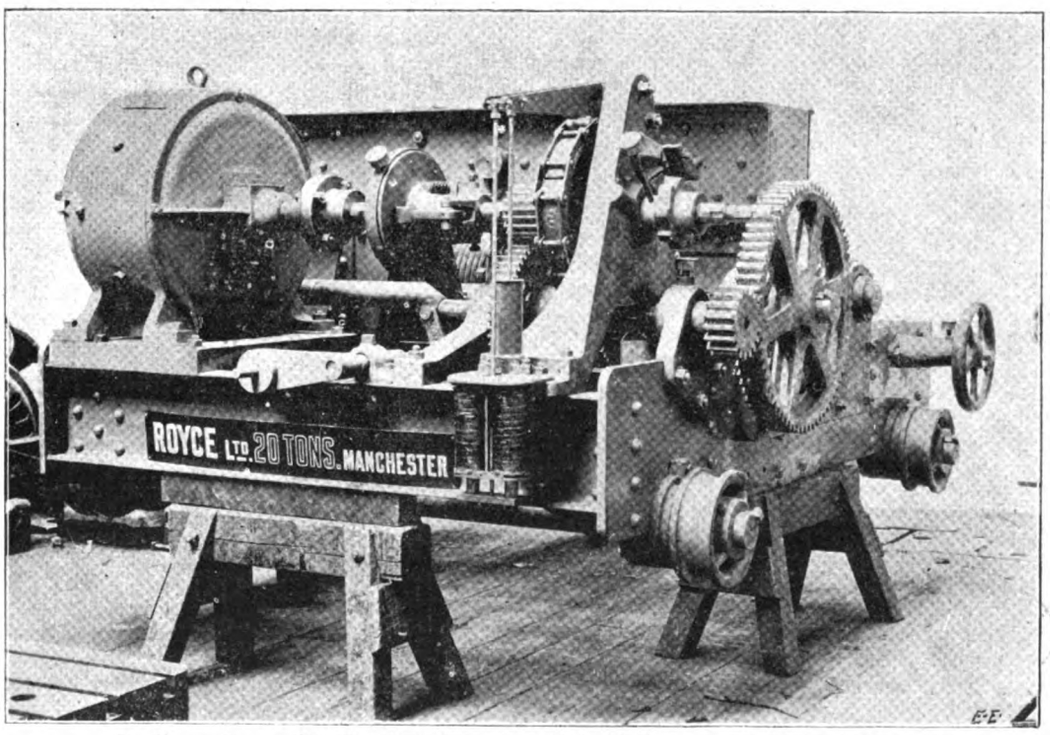

FIG. 11.—A "Royce" 20-ton Electrically-Driven Crane Crab with Change Gear, Trafford Park Works.

Digitized by Google

of current fail, or be interrupted from any cause whatever, an automatic magnetic brake comes into immediate action, whereby the load is securely held in whatever position it may happen to be. Or should either of the controllers become inoperative, an emergency switch placed within instant reach of the driver can be used.

The three-motor 10-ton crane shown in Fig. 9 combines all the features mentioned above. This particular crane has now been shipped to India. It was in course of dismantlement at the time of our visit to the works. A nearer view of the crab of this crane is shown in Fig. 10. The 10-ton travelling cranes comprised in the equipment of the works are of similar design. A "Royce" 20-ton electrically-driven crane crab, fitted with change gear, is shown in the last of the accompanying illustrations (Fig. 11).

But in this department Messrs. Royce by no means confine their attention to the overhead travelling type of crane—Goliath and jib cranes, elevators, hoists and winches, capstans, etc., of their own design and make being also very largely used throughout the country. Probably the success of these cranes, etc., is quite as much due to the perfecting of the mechanical details as to the excellence of their electrical equipments. For example, the bearings of the axles carrying the runner wheels of the crab in a travelling crane of the firm's manufacture are not only swivel but also of the roller type. It is attention to such details that tells in favour of a particular make of article, and full credit is due to Messrs. Royce for having recognised this in regard to their various specialities.

INDEPENDENT TELEPHONY IN GREAT BRITAIN.

BY GARDNER AND HOLME

(Continued from page 846.)

(7) JUNCTION AND TRUNK LINES (*concluded*).

Arms.—These should be of well-seasoned oak, 78in. by 3in. by 2¾in., dressed and bored to take eight $\frac{11}{16}$in. insulator bolts, also pole and $\frac{7}{16}$in. combiner bolts, and given two coats of good paint before leaving the stores. They should be fitted fully 1½in. into the pole, the slots being cut and formed 12in. apart from centre to centre and 9in. from the head of the poles, care being taken to fit the arms tightly and parallel to each other and at right angles to the pole. Galvanised iron bolts and washers are used for fixing the same to the pole, generally ⅝in., and spanners used to tighten all bolts. Workmen generally are careless and neglectful as regards the use of spanners, and in most cases attempt to do pole fitting and mounting with a pair of heavy pliers.

Roofs.—Galvanised iron roofs are generally used for the protection of the head of the pole. In many instances, however, ornamented iron or wood finials are fitted when entering villages, these giving a much better appearance and finish to the poles. In past years it was customary to cut the iron roof for the purpose of fitting a saddle which carried a single insulator, thus giving a better appearance than the plain uncut roof, but the present day of metallic circuits has done away with the use of saddles, as it is imperative in telephone junction or trunk work to erect the wires so as to form exact squares.

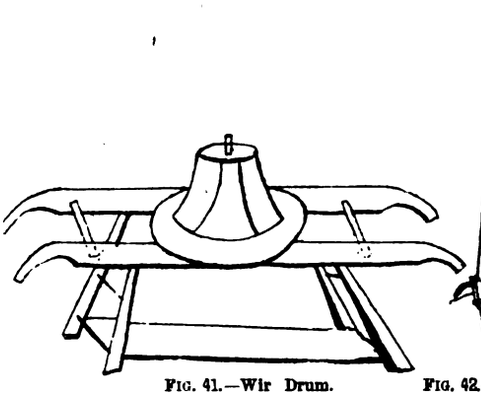

FIG. 41.—Wir Drum.

FIG. 42.—Climbi Iron.

Pole Steps.—Galvanised iron pole steps ought to be fitted on all large poles, especially on poles through villages, the general or minimum height of fitting being 15ft. from the ground, galvanised iron coach screws being used to fit the pole steps to the poles.

Insulators.—The "Bennett" pattern is most suitable for telephone work, as the wires can be made off on different grooves, either top or bottom, and yet be well insulated. They are also not so liable to breakage from stone throwing and are very neat in appearance. The screw insulator should be used and care bestowed on fitting, so that the spindle which screws into the cup is provided with a suitable indiarubber washer, and the cup is firmly secured down upon it. The nuts of the spindle should be screwed up with suitable spanners and not by hand pressure on the cups.

Wiring.—The poles being planted, mounted, and insulators fitted, next follows the actual wiring of the lines. On junction lines No. 14 S.W.G. hard-drawn copper wire, 100lb. per mile, is used. The coil of wire

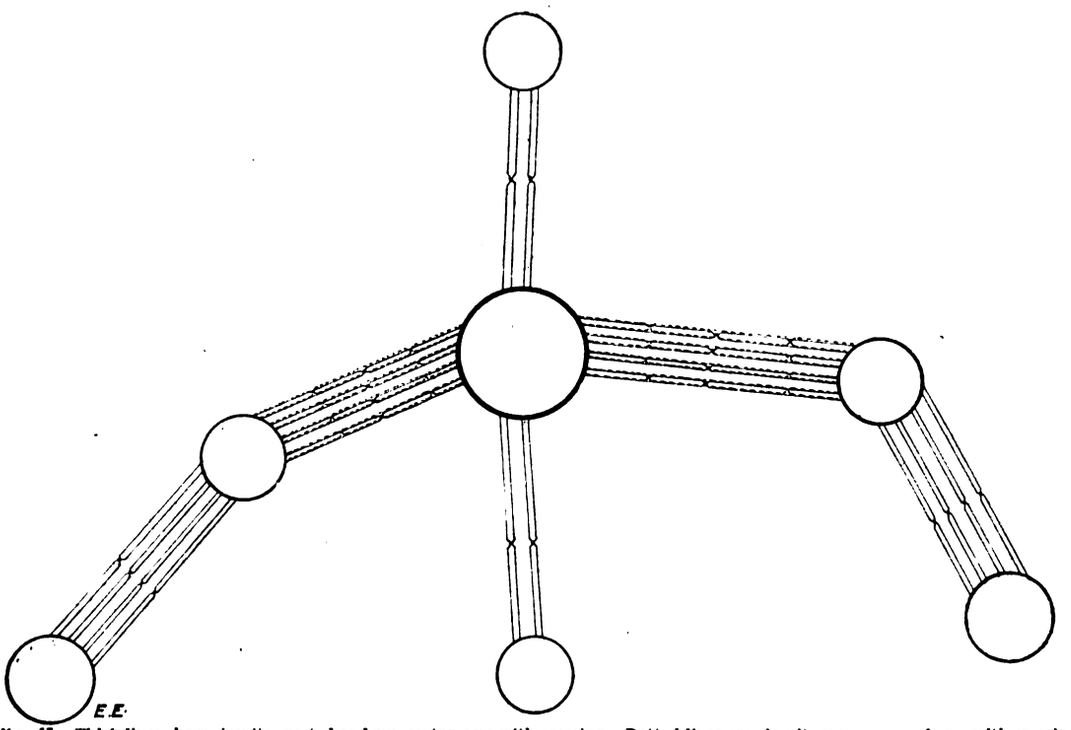

FIG. 43.—Thick lines show circuits erected and run on top arm with crossing. Dotted lines are circuits run on second arm with crossing, midway between that of the top crossing.

Digitized by Google

being placed on a hand drum, as shown in Fig. 41, one man is left to see that the drum does not rotate after the strain on the wire ceases, as this would cause kinking. If the wire is allowed to run off loose, it forms into bights, which will pull up and break when attempting to straighten. The loose end of the coil is taken from the drum and carried away in the direction it is proposed to take. The wiremen should take the side of the road which is clear of traffic, preferably the green sward which usually exists between the pole position and the edge of roadway. He should stop at intervals to allow another wireman following up to carry the wire to the pole-head and place same in position. The quickest method of lifting the wire into position is by means of climbing irons, as shown in Fig. 42, although many engineers are against this method, and insist on ladders being used. Another method, and where the heights of the poles will allow, is to use what are known as contact rods, these rods being made of light bamboo, fitted together by brass tube joints and reaching to a maximum height of 30ft., when used from the ground. They are also used for the purpose of clearing the wires from trees and small branches. The process of paying out and lifting to the pole-head is continued until the coil of wire is all run out, or until the number of spans in the section are wired. The wire is then fixed at one end of the line of poles to the insulator by a make-off joint, then pulled up by hand, and made off temporarily until the desired number of wires or circuits are run. Temporary line stays being fixed to the poles, the wires are next strained up to a uniform tension by means of a hand vice provided with a registering tension ratchet, in order that the system of regulation may be uniform throughout. In straining up any wires for overhead purposes, care must be exercised to avoid injury through nicking off or over-tight squeezing, as once the skin of the wire is injured the strength is impaired. Various stresses and sags for spans to be observed in erecting copper or bronze wires are given in many text-books, so that it is not necessary to enter into the details, but the facts that the temperature and length of span play important parts should not be overlooked. On a line of poles one wire should be pulled up and strained with the tension ratchet to the recognised tension, so that all other wires added will be similarly strained if regulated to the same curve or sag as the first one. It is always best to adjust and bind in all the lines on an arm simultaneously, as the strain on the wires will pull over the arm unequally and destroy the appearance of the head of the pole, if not done so.

Binding In.—The wires are next bound in to the groove of the insulator, the line wire being laid in on the inside next to the pole, with the exception of, firstly, insulators on sharp curves, and secondly, the two insulators next to the pole, the wire in these cases being laid in on the outside of the insulator. Semi hard-drawn copper wire, or, preferably, copper tape, should be used for binding in. In running wires, great care must be given to the temporary staying of the poles longitudinally, so that should there be more strain in one direction than in the other, the temporary line stays will keep the pole in position until rectified by the continuation of the running of the wires.

Jointing.—For large gauge of copper wire the "Britannia" joint should be adopted, as no other method has yet surpassed it, although many forms of patent sleeve joints ave been tried.

Crossing of Roads.—The number and length of the poles will vary according to the number of wires which they eventually will carry. For short lines carrying only one line or metallic circuit, 18ft. to 20ft. may be adopted in the straight, but on junction or trunk lines the number should never be less than 25. Their length will depend not only on the ultimate number of circuits to be carried, but on the buildings, obstacles, and trees to be cleared. Generally on clear roads 26ft. is the minimum length, the lowest arm never being less than 20ft. from the ground, and at all road crossings of any description the minimum is raised to 30ft. This variation should take place gradually, the appearance of the line thus being maintained, and the stress which would otherwise be thrown upon the insulators and wire avoided. For instance, if on a line of 26ft. poles the necessity arose for employing a 30ft. pole, the pole on each side of it should be 28ft. The wires at all road crossings should be made off and all joints soldered. All wire ends and cuttings of copper wire during wiring should be collected and brought into the stores, the foreman being instructed to give this point his special attention, and check from time to time the outside stores under his charge to prevent waste and careless handling. The method of erecting telephone wires for junction and trunk lines in this country consists in causing the wires to twist or revolve clockwise round one another like the strands of a rope, the wires making a complete revolution in every four spans. This method, although answering the purpose of destroying induction, has many drawbacks, such as the liability of the wires to come in contact, and also tracing faults is made more difficult. For short junction lines wires run on the straight with transpositions or crossings at regular intervals answer perfectly. This method was adopted by Mr. A. R. Bennett many years ago, and if understood and carried out correctly works excellently. There are many points in its favour as against that of the twist system, the principal being the rapidity with which faults are located and cleared, and the repair of complete breakdowns, owing to the wires being more easily traced, repaired and regulated. Four metallic circuits may be run on the same arm, the circuits having their crossing made at the same poles by double J insulators. The same number may be erected on the second arm, but in order to destroy the inductive influence more crossings should be introduced than on the upper arm, as will be seen from the Fig. 43. The full lines represent the top arm, and the dotted lines the second or underneath one.

Aerial Cables.—These have become a necessary part of pole line construction, and are more convenient to handle than an equal number of open wires, and with central battery systems reduce the trouble which arises through contacts and earth faults. If well erected and tested in the first instance, they give no trouble till they wear out. On junction lines with a small number of circuits, and where difficulties are met through trees, the cheapest and best method is to use aerial dry-core cable, generally from 6 to 18 pairs being found ample. Aerial cables cannot be handled too carefully, and in erecting every precaution should be taken to prevent injury. The steel suspender should be erected, and a man stationed on each pole of the route. As the cable is run off the drum, the man at the drum fixes the clips, and as these clips come up to the man on the first pole he hooks some of them on the suspender wire, about every fourth or fifth being sufficient. Great care should be taken to see that the cable is not run off quicker than required. As the cable is drawn to the next pole the man unhooks the clips, assists the cable past the pole on to the next suspender, the same operations being repeated at every pole until the cable is suspended in place. Then all clips are suspended on the wire. Overhead cable presents many advantages over the use of open wires, but in many instances it becomes a question of cost as to whether it is not better in the first instance to place same entirely underground.

(To be continued.)

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

643. A country town of about 5,000 inhabitants has a power company's high-tension mains passing through it from which it could obtain power—high-tension three-phase—in bulk at a fixed rate. State the advantages and disadvantages and compare the costs of distributing energy on (*a*) direct-current, three-wire system and (*b*) low-tension, three-phase, four-wire system, the lamp voltage being same in both cases.—V.

644. What are the methods of regulating the voltage on each leg of a three-phase, four-wire distribution, and also of balancing the same?—V.

ANSWERS.

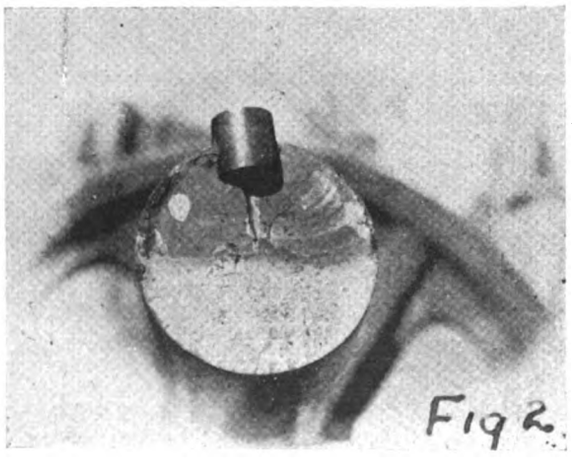
[The following answer to No. 633 was accidentally omitted from last week's issue.—ED. *E. E.*]

Question No. 633.—Several car axles of an electric tramway have broken lately, all *exactly* in the same place—viz., ½in. inside keyway of gear wheel. Upon examination of these and other axles they show signs of being eaten away by electrolysis. Describe a remedy for this, also the action of the electric current upon the axles. The motor box is used for the earth return.

Answer to No. 633 (*awarded* 7*s.* 6*d.*).—Broken car axles have become quite common of late in some towns since the adoption of electric traction. They occur more on narrow-gauge lines than the standard 4ft. 8½in. We in England do not seem to have quite got away from the old horse car practice, in that not enough allowance is made in the size of the axles for a modern 10-ton, four-wheel, double-deck car (strength being by far the most important point to consider) as compared with the now old-fashioned, easy-going horse car of only about 2½ tons, where lightness is really the chief consideration.

FIG. 1.

The breakages, no doubt, are caused by having too small an axle, which will not stand the severe shocks caused by rounding 35ft. and other radius curves at a fairly high rate of speed; also the fact that part of the weight of the motors is carried direct on the axles without a spring support, which makes the hammering effect of passing over bad rail joints and other irregularities of the track much more severe. These undue strains no doubt cause small fractures to start until the axle finally breaks asunder. I have examined about 30 axles that have broken just inside keyway, and have seen no signs of electrolysis. Neither should I think that the "juice" would have any perceptible effect on them. As is well known, electrolysis only sets up when the current leaves a metal, which would certainly not be under the gear wheel, where they usually break.

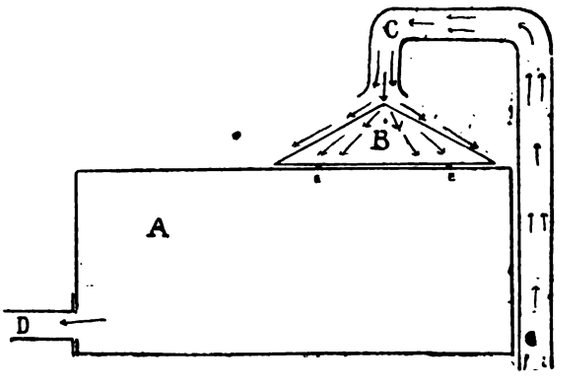


Axles should not be less than 4¼in. in diameter for the type of car referred to above, more especially if the system is very hilly and has many sharp curves. If the axles now in use, say 3¾in. diameter, cannot be increased in size throughout their length owing to the motor suspension bearings, they should be replaced when broken by axles enlarged at keyway end (Fig. 1) to, say, 4⅜in. or 4½in. diameter, the truck and gear wheels being bored out to suit. This has been done on a certain tramway system I am connected with, and so far with success. When new cars are being ordered, however, it would be advisable to specify a larger axle as before mentioned. I may add that we have tried cold-rolled steel axles, but with little success, as they bend too easily and so cause the cars to roll.

The reproduction (Fig. 2) of a photo taken of one of our first broken axles shows very clearly the flow about halfway through set up by the enormous strains and shocks it had been subjected to. The end of the gear wheel key is seen projecting.—MAGNUS H. VOLK.

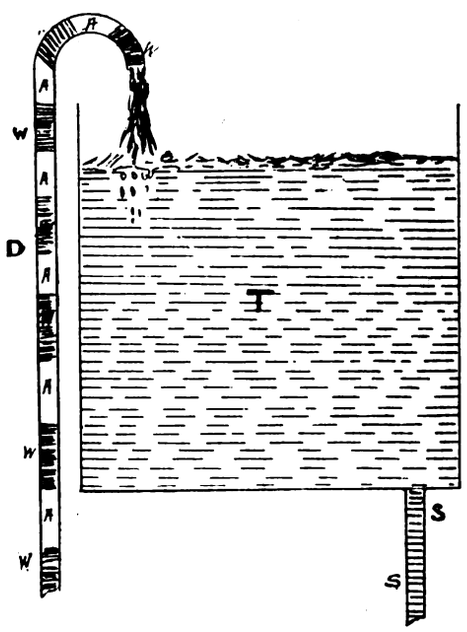
Question No. 635.—Describe some method of extracting air from water to be used for condensing purposes, the water having been raised from a borehole by compressed air.

Answer to No. 635 (*awarded* 7*s.* 6*d.*).—Connect supply pipe, C, from borehole to deliver water into tank, A, fix a cone-shaped distributor, B (preferably made of galvanised iron), on two supporting bars, E E, so that it is directly under the centre of the bellmouth of supply pipe, C. This cone should not be less than 6ft. diameter and about 2ft. high.



The water will then flow uniformly over the whole surface of the cone in a thin stream, and all air contained in the water will be set free. D is the supply pipe to condenser.—B. S. H

Answer to No. 635 (*awarded* 7*s.* 6*d.*).—In raising water from a borehole by means of compressed air, the air is not, as is very often supposed, thoroughly mixed with the water which it raises, but is disposed somewhat in the manner shown in the sketch. D is the delivery pipe, or "rising main," as it is termed; the shaded portions, W, represent



water, and the blank spaces, A, represent air. It will be noticed that there are alternate columns of water and air. It will be obvious from this sketch and the short description of the action which takes place in raising water by compressed air that, if the air is given a chance, it will escape. The diagram shows a method whereby the air is given every facility to escape. D is the delivery pipe, delivering downwards into the tank, T. This tank should be made of as large a capacity and as deep as circumstances will permit. The supply to the condenser is taken from

Digitized by Google

pipe S, which is fixed, as shown in the diagram, on the opposite side to the delivery. By making the tank of large capacity and as deep as possible, a large reserve of water is kept, and as the agitation caused by the force of the water delivered to the tank is confined to the surface of the water in the tank, it will be apparent that the water has every chance to settle, and the air every chance to escape, before the supply pipe, S, is reached.—W. T. W.

Answer to No. 635 (*awarded* 5*s.*).—If only a comparatively small quantity of water is required, it could be subjected to a reduced pressure in a closed vessel. Under an approximate vacuum any gases dissolved in the water would quickly escape. On the other hand, if large quantities of water are used, it would be better to treat the water with some substance in order to absorb the gases present, with precipitation of salts and other deleterious matter; this matter to be afterwards removed by filtration. It has been found satisfactory to pass water through horizontally revolving cylinders in which was placed a quantity of cast-iron borings. A series of baffle plates are fitted to the inner surface of the cylinders, in order that the borings may be thoroughly mixed with the water. The process is: iron borings converted into ferrous oxide by the oxygen in the water, ferrous oxide partly dissolved by carbonic acid gas as bicarbonate, the latter being easily converted into ferric oxide. The ferric oxide precipitates, carrying with it any suspended matter in the water. This precipitate can be filtered out or allowed to deposit in settling tanks, the top water in the latter case being employed for condensing.—M. M.

Question No. 636.—Give sketches of how you would arrange to control a pump and motor of 2 h.p., 550 volts, two miles away to indicate when the water was at maximum and minimum height.

Best Answer to No. 636 (*awarded* 10*s.*).—"G. H." does not say whether the current is supplied from the controlling station, but it is to be presumed it is. First as to the control of motor. A 2-h.p., 550-volt motor can be controlled by a switch and resistance box without special field wire, but a series motor is preferable. As to showing maximum and minimum height of water, many devices are in use for this. Most of them rely on floats, with rods, chains, or wires actuating a variable resistance. A galvanometer at the far end is graduated in feet, and thus reads the height in the reservoir. Unfortunately, the resistance, owing to the damp surroundings, often takes to varying on its own account, irrespective of float, etc., and has been known to put the engineer in a cold perspiration and send him to the window expecting to see a roaring flood rushing down the road. Others, again, need a dozen wires, which are blown down every winter, so that it is less work to walk the two miles and look at the tank. Fig. 1 illustrates a method in which two wires only are used. Above the dotted line is one station, below the controlling station. A B A_1 is a pressure gauge reading in pounds per square inch to half the height of the reservoir in feet. On the dial are screwed two pieces of vulcanite with nickel contacts. The pointer has platinum contacts soldered on either side. The mains to the motor are shunted to this gauge, which should be on the level of the bottom of the tank, and placed in the motor and pump room. It should be hermetically sealed. At the controlling station is an ordinary starting switch, F. Across the mains are connected four 16-c.p. 250-volt lamps earthed at the middle, while in series with these is a maximum cut-out operating with ¼ ampere, and short circuiting the holding magnet, F. The operation is as follows: On gradually starting F the motor will start. As the pressure rises the pointer, B, will gradually turn till, when the reservoir is full, B will touch A. Now B is earthed, as shown, hence the lamps, G, will light up, the maximum cut-out, D, will operate and switch off the current. To tell whether the reservoir is full or not, the engineer, on returning, has but to glance at the lamps. When the reservoir empties B turns back to A_1, and the lamps, H, light up to warn it is time to start up. This method will not do on a three-wire system, or a botched job with odd earths here and there. If the height at any moment is desired, a gauge, as in Fig. 2, may be used. The pointer has a small nickel wheel rolling on contacts on each side. These contacts have resistances, as shown, wound inside the gauge. As one resistance goes out the other goes in. All is hermetically sealed. To the pointer (frame) is

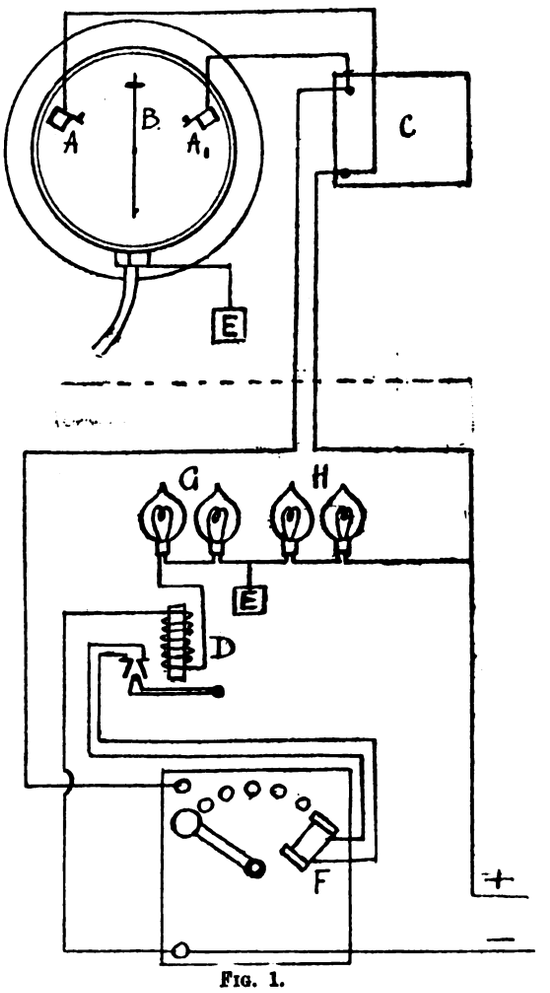


FIG. 1.

connected a four-cell battery with the zinc earthed. At the receiving end is a differential galvanometer calibrated in feet, the common terminal of the coils being earthed. This will show the height at any moment, a switch

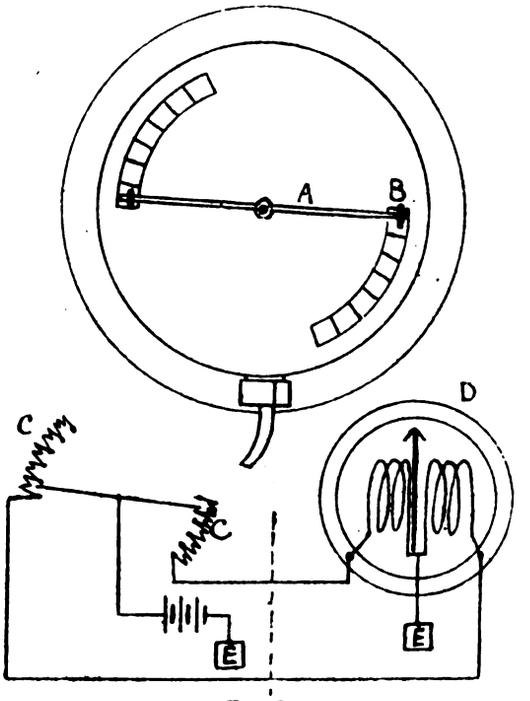

FIG. 2.

being used to make the test when required. Thirdly, if "G. H." wishes to merely control the current, he may control the motor by means of the water itself. In Fig. 3, A A_1 are two copper cans fixed on an arm and connected to

Digitized by Google

a shaft. This shaft is carried back from the tank to the motor starting switch, which has a no-load release. At the top of the reservoir is an overflow pipe, B, carried down to A, and near the bottom is a valve, C, with pipe over A_1 (ordinary cistern ball-valve). When the water falls to within an inch of C, C opens and gradually fills A_1. It slowly falls against the starting switch, E (Fig. 4), the contacts being rounded to make sure of no middle stops.

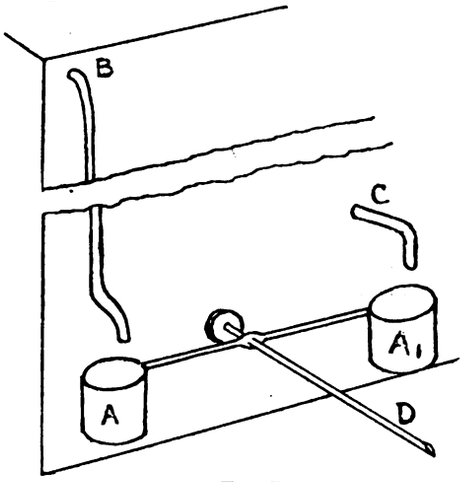

FIG. 3.

Finally, the no-load release magnet grips the switch handle. When the reservoir gets full it overflows and water flows into A. Now in both A and A_1 two small holes are drilled in the bottom, so that A_1 is now empty. A gradually fills, and at last forces the no-load release magnet to let go. The motor is immediately switched off. The same routine is gone through each time the water falls and rises, but the following precautions are necessary: the valve, C, should not open too slowly; make it just tight enough to act jerkily; the overflow from A and A_1 should be led back to the pump well; a starting resistance should be placed at the controlling end if the current is to be cut off at intervals; an ammeter at the controlling end will indicate whether the tank is being

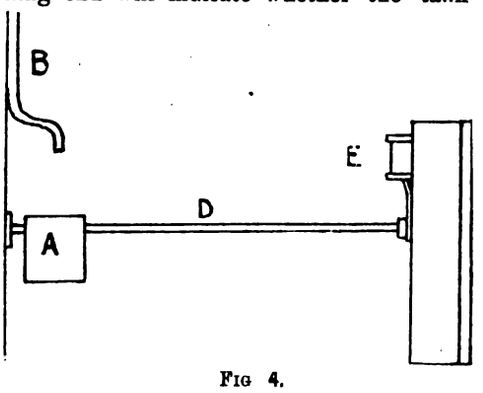

FIG 4.

filled or is full, as when the motor is going it is filling and when stopped is falling.—POLYPHASE.

Answer to No. 636 (*awarded 7s. 6d.*).—"G. H." can accomplish his task in innumerable ways, each, perhaps, suited to some particular case. The following three diagrams, however, treat the question from as many different standpoints, and he may therefore be able to modify or augment one of them to fit in with the special circumstances, if any, of his particular case.

In Fig. 1 we have the full control of the motor at the supply end of our two miles run of mains. Presume that the motor, M, is running, in due course the ballcock, B C, on the end of the pump discharge pipe will begin to close, putting gradually increasing resistance against the pump, and, of course, causing the motor to absorb more and more current. By suitably adjusting the overload on the hand-operated motor starter, M S, the motor circuit will be broken by the opening of the overload when the tank, T, is full. When the water falls sufficiently the lever arm of the float switch, F, will throw over the weighted arm and close its circuit through the four incandescent lamps, L L. (These are connected as drawn to obviate risk of failure through any one lamp burning out.) In this arrangement we have, therefore, a visible signal at each end and the ringing of the bell—wound for the case in question—at the supply end. The contacts on the rope which operates the float switch should be so adjusted that the switch will return to normal when the water-level has risen even very slightly.

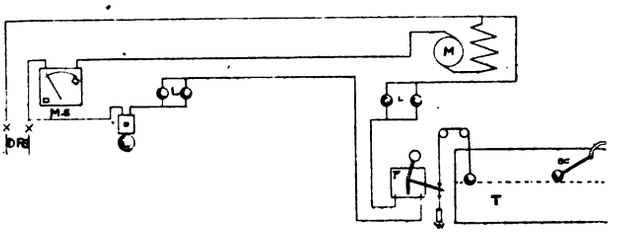

FIG. 1.

Fig. 2 shows an entirely automatic arrangement, and although the rheostat is drawn as being at the supply end, it may be put close to the motor if desired. When the water in the tank, T, becomes low, the float switch, F, is operated as before. The closing of the circuit excites the solenoid main switch, S M S, which in turn closes the motor circuit. If the maximum cut-out, M C, is already closed, the automatic rheostat, A S, will gradually cut out resistance, bringing the motor, M, up to speed. Provided the contacts on the rope attached to the weight, W, are so adjusted, the

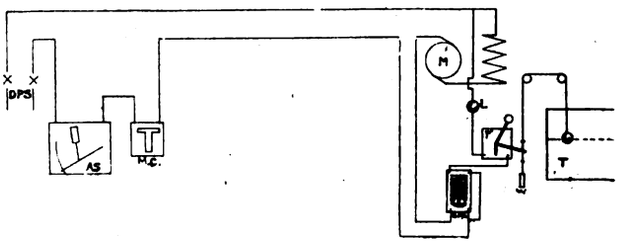

FIG. 2.

float switch will be opened when the tank is full, the main circuit consequently being broken at S M S, and the motor will come to rest.

In Fig. 3 is shown a signalling system, where C_1 C_2 are fixed contacts, each composed of two pieces of metal which are short-circuited by the conical contact piece, C C, fixed to the rope and weight, W. Accordingly as to whether

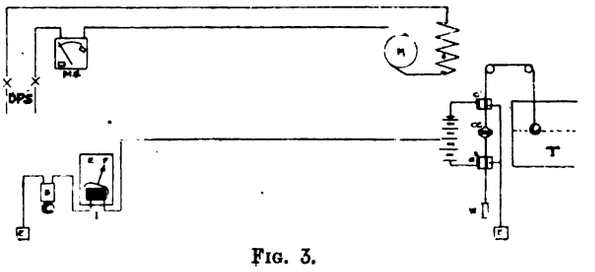

FIG. 3.

the upper or lower pair of contacts are short-circuited, the indicator, I, points to E or F, signifying empty or full, and the bell, B, is put in action. This bell will continue to ring until the water is at a more normal level, unless switched off. This arrangement, as will readily be seen, is capable of almost unlimited modification, and may very easily be used in conjunction with almost any mode of control. It may be as well to state that float and other automatic switches referred to above may be obtained from the Sturtevant Company.—F.

Answer to No. 636 (*awarded* 5*s.*).—The most suitable way would be as shown in Fig. 1. When the float is at top of tank, tank consequently being full, current is cut off from the motor by means of the switch, S. This switch is arranged to start and stop the motor at any specified depths of water in the tank by adjusting the tappets, T and T^1, on the chain that carries weight and float. It will be noticed that the switch is fitted with a balance weight. When brought just past the vertical this weight flies over, giving a quick make and break. In both figures motor is shown cut out of circuit. Suppose water were drawn from the tank float would fall

Digitized by Google

and weight rise. Tappet T¹ would then engage with lever and carry balance weight on switch to the vertical position; balance weight would then fly over, giving a quick make. Solenoid being energised, starting switch lever is drawn over contacts gradually cutting out resistance and motor

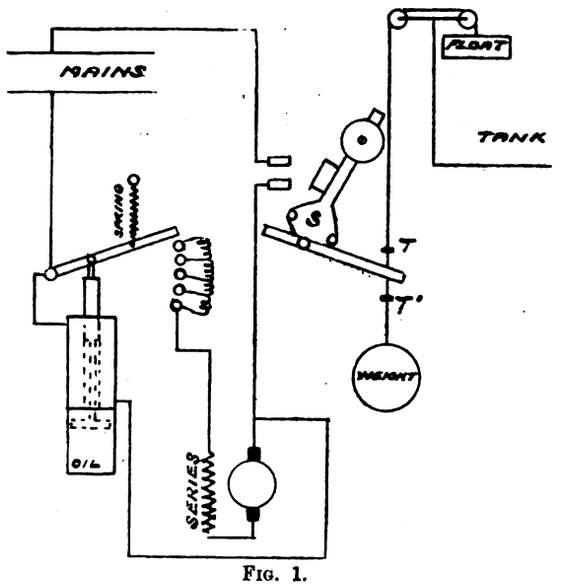

FIG. 1.

brought up to full speed. The solenoid must be so wound that it may bear the full potential of the mains across its terminals continuously without injury; it is fitted with a dash-pot to prevent starting resistance being cut out too quickly. Dash-pot, piston, and connecting piece between piston and core of solenoid must be made of brass or gunmetal. An instrument fitted as shown in Fig. 2 would give a record of the time motor was running. The drum, D, driven by internal clockwork, carries a paper on which a record of the current passing is traced by a pen at the end of the index, I. The iron armature is attracted over, in proportion to the current flowing, to the motor passing round the electromagnet of the instrument. When motor started the current could be

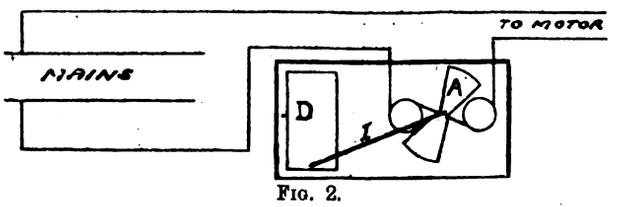

FIG. 2.

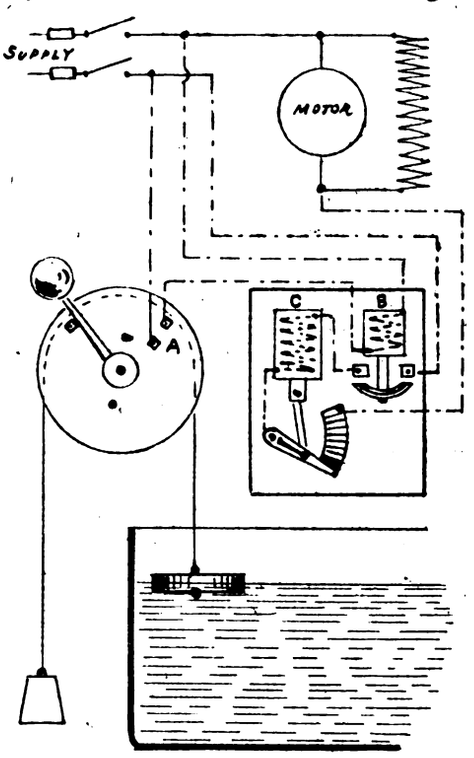
made to ring a bell to call attention to the fact that the motor was running.—M. M.

Answer to No. 636 (*awarded* 5*s.*).—Assuming that "G. H." wishes to raise water into a tank by means of the 2-h.p. motor, and does not wish to keep an attendant on the spot to stop and start it as required, the best way is to instal an automatic arrangement as shown. If it is a country district and on private ground, the leads from source of supply could be bare copper wire on porcelain insulators carried on pine poles. The leads should be protected by double-pole fuse and controlled by double-pole switch, and then run direct to starter, and coupled up as shown in diagram. The action is as follows: When level of water in tank falls, the float actuates a switch, A, which closes the circuit of a solenoid, B, and this switches on current to motor with all resistance in series with the armature. The current passing through armature also passes round solenoid, C, which gradually draws up the switch arm, and cuts out resistance as motor comes up to speed. When the tank is full the float rises and opens switch, A, cutting off current from solenoid B, and this immediately opens main switch, and cuts off current from motor and solenoid C; therefore, switch arm will be released, and all resistance cut in armature circuit ready for starting again, when water is drawn off from the tank. I believe the Sturtevant Engineering Company, of London, supplied the apparatus I have described. By observing an ammeter placed in circuit with motor leads it could be seen when motor stopped, which would indicate maximum height of water;



also when motor started, which would indicate minimum height.—A. T.

BALLADS OF BUSINESS.

No. 4.—Some Specifications, and a Suggestion.

No. I.

The manager reviles it,
It's sworn at by the Works,
The estimater's verdict
This pen description shirks.
And whosoever reads it
Says, as a general rule:
"It's written by an idiot,
And it's printed by a fool."

No. II.

It's fat and very wordy,
It's full of legal jaw,
It threatens one with penalties
And processes of law.
It wants a ton of samples,
Till one feels, a trifle riled,
That it's written by a father
For a very naughty child.

No. III.

Like visits from the angels
It comes, if not so rare;
It tells you what you wish to know
Without the aid of prayer.
Its plans are clear and ample,
Its schedules clear and few;
It's written by a man who knows
Just what he wants to do.

The Suggestion.

O! prithee, good consultants,
Upon whose words we hang,
To cultivate the Jingle style.
If not the Andrew Lang.
But, should you deem it *infra dig.*
To alter what you've done,
Add here and there a Limerick
And here and there a pun.
'Twould help to cheer those pages drear
If sprinkled o'er with fun. B. C. H. J.

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to July, 1903, now ready.*

BELGIAN RAILS.

The excuse put forward by Mr. Benn during the discussion on Lieut.-Colonel Rotton's motion at the meeting of the London County Council last Tuesday was childish in the extreme. It consisted of, so far as the published reports go, "We were not the first nor are we the only ones to buy in the cheapest market." Colonel Rotton proposed: "That it be referred to the Highways Committee to ascertain and report to the Council (*a*) the number of hours of labour per week worked by the men employed by the Belgian firm in making rails for London tramways, and (*b*) the rate of wages per hour paid to such men, and if they do any work on Sundays in connection with the manufacture of such rails."

An amendment was moved by Mr. McKinnon Wood as follows: "That it be referred to the Highways Committee to ascertain and report to the Council (*a*) the number of hours of labour per week worked by the men employed in foreign firms in making rails for the Government, provincial corporations, London tramways, and railways; (*b*) the rate of wages per hour paid to such men, and if they do any work on Sundays in connection with the manufacture of such rails; and (*c*) the amount of mining royalties paid by foreign firms as compared with those paid in Great Britain."

The amendment was carried by a large majority without a division. We entirely agree with one of the speakers, that the amendment is calculated to smother the whole enquiry. The London County Council might just as well have added another clause, to the effect of seeking to know the age when elephants cut the eye teeth, or whether they have any eye teeth. What has the London County Council to do with other corporations' orders? It has its own sins of omission and commission to answer for, and that is enough. We have said before, and we say it again, as emphatically as possible, the London County Council on this question shows the grossest ignorance. It is within the last few years that a deputation of British ironworkers went to Belgium, with Mr. J. S. Jeans, if we remember aright, as secretary. This deputation issued a report containing most, if not quite, all the information required relating to wages, methods, organisation, etc., to be found in Belgium. If Mr. Benn and his coadjutors did not know of this report when they were determining the clauses of their specifications in contracts, they ought to have known it. The following are the terms of the contract embodied in Clause 34:

34. The contractors, notwithstanding Clause 33, may sub-contract for all or any of these portions of the work to be executed by them under this contract, which comprises the manufacture of the track rails, slot rails, and conductor rails, etc., subject to the following conditions and provisions which the contractors hereby agree to observe, perform, and fulfil—*vide licet:*

1. That sub-contracts shall be made with such person or firm or firms only as shall have been first approved by the engineer.

2. That no sub-contract shall operate to relieve the contractors from any of their liabilities or obligations, and that the contractors shall be responsible for all the acts, defaults, and neglects of the sub-contractors as fully as if they were the acts, defaults, and neglects of the contractors.

3. That there shall be inserted in each sub-contract a covenant by the sub-contractor (1) that he will pay all workmen employed by him in or about the execution of such sub-contract wages at the rates arranged between the employers and workmen in the rail trade in that part of the kingdom of Belgium or other country where the order is placed, with such approval as aforesaid; and (2) that such sub-contractor will at all times during the continuance of the sub-contract, whenever called upon to do so by the clerk of the Council, produce to such officers of the Council

Digitized by Google

as the clerk may direct the time and wages books and sheets of the sub-contractor to show whether or not this stipulation has been and is being complied with.

4. That in case of any breach by the sub-contractor of the covenant as regards rates of wages to be inserted in any sub-contract (and notwithstanding the connivance of the contractors of such breach or any prior breach), the Council shall have power to cancel this contract so far as it relates to any part of the work not totally or partially manufactured whether by the contractors at any time on one week's notice to the contractors.

Is it Mr. Benn's view of equivalence of wages and time incidence in Britain and Belgium, that if local conditions are complied with all is well? The labour members are against him, for Mr. Steadman, a labour member, speaking on the first order in the Council on March 4, 1902, is reported to have said: "If you force organised labour in this country to demonstrate by its strength that it is enabled to get an increase from the employers, then, on the other hand, you have no right to turn round and blame organised workers for your sending contracts to a foreign country in consequence of the conditions which you yourselves have laid down. Now, sir, I shall be told that I am advocating protection. Yes; but protection of what sort, sir? I am advocating a protection which, if I had not taken the stand I am taking on this particular thing, I should be unworthy to occupy the position that I am now occupying in the great trade union movement in England to-day. Yes, sir, I am going to stand up—and you can call it protection as much as you like, but I intend to stand up and fight for the protection of British labour as against the sweated labour on the Continent."

Mr. Benn and such as him combine to force higher wages and shorter time in this country; hence impose conditions upon masters which have to be met by higher prices, and when these prices are quoted they practically say, "Pay your wages and keep your factories going if you can. How you can do it we neither know nor care, but one thing is certain, you won't get higher prices from us. Oh, we buy in the cheapest market." In his reply, Colonel Rotton said that Mr. Benn had not faced the music, but danced round it. The whole of this question is closely connected with the hitherto generally accepted doctrine of supply and demand. For some years past the natural course of supply has been interfered with, hence these troubles. It is easy to gain a temporary popularity by playing down to the passions and prejudices of the *oi pollio*, but Nemesis is sure if tardy. You cannot artificially inflate wages unrestrictedly without the effect being shown sooner or later. Men do not like to acknowledge the error of their ways, hence try to find a thousand excuses for their actions except the right one. How does Mr. Benn know that the conditions he imposes in this country are natural? If they are not, he is wrong in this matter. We think he is wrong, because the costs of rail production have again and again been analysed, and are known to the remotest decimal of a penny, and the excuses he puts forward have been also proved to be wrong. Our large steel manufacturers are owners of iron and coal mines, and hence do not pay royalties, so that the fiction of royalty addition is merely to draw attention from the real point. Given equivalent machinery, equivalent raw materials, on the one hand, with added higher wages and shorter hours, and the product cannot compete with longer hours and lower wages.

Newcastle Local Section.—At the ordinary meeting of the Newcastle Local Section of the Institution of Electrical Engineers on Monday, Dec. 14, a paper entitled "Experiments with Eddy Currents" will be read by Mr. W. M. Thornton.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

STEAM TURBO GENERATING PLANTS.

SIR,—As managing director of the Cambridge Electric Supply Company, Limited, and also of the Scarborough Electric Supply Company, Limited, and as, therefore, in some measure responsible for the exclusive and continued use of steam-turbines by these two concerns, I feel called on to draw attention to what appears to me to be the entirely misleading nature of the comparisons between the results obtained in steam-turbine stations on the one hand and reciprocating engine stations on the other, recently published in your columns by Messrs. Belliss and Morcom.

For their purpose Messrs. Belliss and Morcom state that they have selected reciprocating engine stations which are "under approximately similar circumstances as to costs of labour, fuel, output, etc.," as the turbine stations. No doubt they have made this selection as fairly as is possible, but to show how unsuccessful they have been in this respect, it is only necessary to point out that among their reciprocating engine stations they have included Salisbury, where a portion of the electrical generation is carried on by means of water power, and where both fuel and works costs are therefore abnormally low. Again, though Messrs. Belliss and Morcom specially mention the matter of output, their own figures show an average annual output of 1,464,907 units for their reciprocating stations and only 738,924 units for the turbine stations—a ratio of practically 2 to 1.

How greatly the mere quantity of output affects results may be seen from the following figures, which show how the costs of fuel, etc., have decreased at Cambridge and at Scarborough as the output has increased in the last seven years:

	Total units sold.	Fuel.	Oil, waste, and stores.	Works costs	Total costs.
Cambridge.					
1895	150,510	1·98	·19	3·91	4·53
1902	419,005	·66	·14	1·57	2·40
Scarborough.					
1895	135,177	1·66	·12	3·47	4·36
1902	431,777	·85	·08	1·61	2·65

Incidentally the above figures also go to show that the efficiency of steam-turbines does not fall off with use, as has been suggested in some quarters.

Another most important omission from Messrs. Belliss and Morcom's figures is any consideration of the question of load factor, which, as all station engineers are aware, has a greater effect upon costs than almost anything else. The following are the load factors of the turbine and reciprocating engine stations selected by Messrs. Belliss and Morcom for the same years that they have given the other costs:

Steam-Turbines.		*Reciprocating Steam-Engines.*	
Blackpool	14·32	Leeds	12·31
Newcastle District	13·67	Halifax	16·98
Cambridge	9·13	Bootle	28·44
Scarborough	9·34	Taunton	12·77
West Bromwich	9·27	Darwen	12·12
Morecambe	7·06	King's Lynn	15·58
Melton Mowbray	11·11	Salisbury	11·49
Average	10·55	Average	15·67

As will be seen, the average load factor of the reciprocating stations is practically 50 per cent. better than that of the group of turbine stations.

To recapitulate, the following are the points to which I desire to draw attention: (1) among the reciprocating stations Messrs. Belliss and Morcom have selected there is one where, owing to the use of water power, the results are abnormal; (2) the average output of the reciprocating stations Messrs. Belliss and Morcom have selected is about double that of the turbine stations; (3) the former have, on the average, a 50 per cent. better load factor than the latter. I think that most engineers will agree with me that, under these circumstances, Messrs. Belliss and Morcom's comparisons are of no value at all.

Lastly, I note that in Messrs. Belliss and Morcom's list of turbine stations they have left entirely out of account

Digitized by Google

that belonging to the Newcastle-on-Tyne Company, which, if I mistake not, is now almost entirely run by means of steam-turbines. Would it surprise Messrs. Belliss and Morcom to learn what I am informed on good authority is the fact—namely, that the works cost of this station are now less than half the most favourable similar figure of ·62d. per unit which Messrs Belliss and Morcom give for Leeds? Now, the cost of coal and labour at Newcastle and Leeds cannot differ very greatly, so this enormous difference must be due to matters of load factor and output, and probably also to some amount of superior economy in steam-turbines over reciprocating engines.—Yours, etc.,

A. A. CAMPBELL SWINTON.

66, Victoria-street, S.W., Dec. 3, 1903.

SIR,—In reply to the bulk of Mr. Wilkinson's reply in your issue of Nov. 27, 1903, we need only refer to the previous correspondence. For the rest, we can assure Mr. Wilkinson that we have had a very large and satisfactory experience with high superheat in our reciprocating engines during recent years, and, as our customers know, have done a great deal of hard work in assisting to make the advantages of superheat practically possible. We omitted Shipley, as we found that they were receiving steam gratis from the destructor works.

Mr. Wilkinson's suggestion that a trial should be made with the best examples of reciprocating engines and steam-turbines, under ordinary central-station conditions as to superheat and vacuum, is, in our opinion, a good one. The difficulty is to get such a prolonged trial made under impartial and useful conditions, but if any of the leading engineering associations are prepared to take the matter up in the interests of their members, we should be very pleased to lend an engine for the purpose.—Yours, etc.,

(for Belliss and Morcom, Limited),
ALFRED MORCOM, Managing Director.

Dec. 8, 1903.

SIR,—Mr. Wilkinson states in his letter published in your last issue that "it is an undoubted fact that turbines give no trouble when working with superheated steam." Now, I have information that about a fortnight since about one-fourth of the total number of blades were stripped off one of the turbines in a station in the Midlands, and the trouble was attributed to superheated steam, and that the blades are to be replaced by others of a metal specially adapted to withstand the effects of superheat. I also know of a similar thing having happened not long since at another station, the failure being also attributed to the use of superheated steam. At this station reciprocating engines were in use as well as steam-turbines, and when subequently extension sets were required, reciprocating engines were installed. I have also heard of the blades being stripped off a large turbine in the States where superheated steam was in use. These sort of experiences are not, as a rule, published in the papers; indeed, it seems almost indecent to drag them into light, but if without any special sources of information I have heard of three different instances of trouble with superheat, no doubt others have occurred which have not come to my knowledge. Perhaps Mr. Wilkinson might say as to experiences he has had with blades being stripped off the turbines at his station —Yours, etc,

RECIPROCATING ENGINE.

THE DIESEL ENGINE.

SIR,—In the first answer to Question No. 634 in the *Electrical Engineer* of the 4th inst., "A. C. G. I." would appear to have got a little mixed. In the diagrammatic drawing shown accompanying the answer your correspondent simply reduces the Diesel engine to a compound expansion engine with two cylinders. He also shows the low-pressure cylinder double acting. It is true that in his earlier experiments the inventor used as many as three cylinders, but the engine which is now upon the market, and which has become a commercial success, is in every respect similar to an ordinary gas or oil engine, having what is commonly known as the Otto cycle, the whole of the work being done in one cylinder, assisted in compression by an air-pump. In the two-cylinder type there are simply a pair (sometimes called twin) of complete engines connected together in the usual manner adopted by the makers of gas and oil engines, and by this means an impulse is obtained each revolution.—Yours, etc., E. F.

FLATS IN COMMUTATOR.

SIR,—I am in charge of a dynamo, 110 volts 40 amperes, and am troubled with a flat constantly coming in one of the segments of the commutator. As soon as it appears I have it turned out in the lathe, but it soon reappears. The coils of the armature appear to be all right. The springs of the brushes are all right. The brushes we use are copper gauze filled in with graphite. I should be pleased for any valuable correspondence on it.—Yours, etc.,

F. J. HOPLEY.

FORTHCOMING EVENTS.

FRIDAY, DEC. 11.

Tramways and Light Railways Association.—At 8 p.m., inaugural meeting. Address by Mr. Atherley-Jones, K.C., M.P. on "Protection in Special Relation to Tramway and Light Railway Enterprise."

Physical Society.—At 8 p.m., at the Royal College of Science. Papers: "A Method of Mechanically Reinforcing Sounds," by Rev. T. C. Porter; "The Simmance-Abady 'Flicker' Photometry," by Messrs. Simmance and Abady; "Exhibition of a Conductometer," by Mr. M. R. Appleyard; and "A Model to Illustrate Various Properties of Wave Motion," by Prof. L. R. Wilberforce.

SATURDAY, DEC. 12.

West Hartlepool Scientific Society.—At 7.30 p.m., ordinary meeting. Paper: "Mr. D. B. Morrison's Scheme for the Advancement of Apprentices," by Mr. Wm. Kennedy.

Glasgow Scientific Society.—At 7.30 p.m., ordinary meeting. Paper: "Steam-Turbine Machinery," by Mr. Arthur A. Wynne, M.A.

MONDAY, DEC. 14.

Institution of Mechanical Engineers.—At 7.30 p.m., graduates' meeting. Paper: "Main and Auxiliary Steam-Pipes for Power Plants," by Mr. Henry Baker.

Society of Arts.—At 8 p.m. Cantor lecture: "The Mining of Non-Metallic Minerals," by Mr. Bennett H. Brough (Lecture IV.).

TUESDAY, DEC. 15.

Institution of Electrical Engineers (Manchester Section).—At 7.30 p.m., ordinary meeting. Paper: "Electric Traction with Alternating Currents," by Mr. A. C. Eborall.

Institution of Civil Engineers.—At 8 p.m., ordinary meeting. Papers: "Deposition in Pipes and other Channels conveying Potable Water," by Mr. J. C. Brown, D.Sc.; "The Purification of Water Highly Charged with Vegetable Matter," by Mr. O. Chadwick, C.M.G.

WEDNESDAY, DEC. 16.

Liverpool Engineering Society.—At 8 p.m., ordinary meeting. Paper: "Polyphase Working," by Mr. H. W. Wilson.

Society of Arts.—At 8 p.m., ordinary meeting. Paper: "Science and Industry," by Sir Wm. H. Preece.

Institution of Electrical Engineers (Birmingham Section).—At 7.30 p.m., ordinary meeting. Paper: "Testing of Electric Generators by Air Calorimetry," by Prof. R. Threlfall, F.R.S.

Royal Meteorological Society.—At 7.30 p.m., ordinary meeting.

Society of Engineers.—At 6.30 for 7 p.m., annual dinner, Hotel Cecil.

Chemical Society.—At 5.30 p.m., ordinary meeting.

THURSDAY, DEC. 17.

Institution of Electrical Engineers.—At 8 p.m., ordinary meeting. Paper: "The City and South London Railway—Working Results of the Three-Wire System applied to Traction," by Mr. P. V. McMahon. Leeds Section.—At 7.30 p.m., ordinary meeting. Paper: "Methods of Charging for Electrical Energy," by Mr. E. H. Crapper.

Engineering Society, King's College.—At 5 p.m., meeting.

FRIDAY, DEC. 18.

Institution of Mechanical Engineers.—At 8 p.m., ordinary meeting. Papers: "An Enquiry into the Working of Various Water Softeners," by Messrs. C. E. Stormeyer and W. B. Baron.

Electro-Harmonic Society.—At 8 p.m., in the King's Hall, Holborn Restaurant, smoking concert.

Institution of Civil Engineers (Students' Section).—At 8 p.m., ordinary meeting. Papers: "The Action of the Sea upon the Foreshore," by Mr. C. B. Case; "The Causes of the Loss of Beaches," by Mr. F. W. Cable.

SATURDAY, DEC. 19.

Junior Institution of Engineers.—At 3 p.m., visit to the electricity works of the Walthamstow Urban District Council. Train leaves Liverpool-street at 2.23 p.m.

THE INSTITUTION DINNER.

The fifteenth annual dinner of the Institution of Electrical Engineers was held in the Grand Hall of the Hotel Cecil on Wednesday last. The President, Mr. Robert Kaye Gray, was in the chair, and was supported by a number of illustrious guests, amongst whom we may mention Lord Reay, Lord Monkswell, Lord Biddulph, Lord Claud Hamilton, M. Hospitalier (president of the Société Internationale des Electriciens), and Mrs. Ayrton (the only lady member of the Institution). A number of the general managers of our leading railways were present. The President and the Council are to be congratulated on the large number of members present, and it is evident that the reorganisation of the toast list is increasing the popularity of this annual function. This year, apart from the loyal toasts, there were only three other toasts to be honoured, and in each case the five minutes' limit to the speeches was strictly adhered to. The result was that at a comparatively early hour members were able to adjourn to the reception room, where the Imperial Orchestra acted as accompanists to the general conversation.

After the loyal toast had been honoured, Lord MONKSWELL, the chairman of the London County Council, proposed in an able speech "The Institution of Electrical Engineers." He referred to the members of the Institution as the spoilt children of science, and of their "earning fame and wealth." We trust that his speech is prophetic.

The PRESIDENT, in reply, mentioned the great work which the London County Council had in hand in converting their tramways for electric traction. This undertaking had the warm approval of the Institution. While admiring the larger works that the Council are engaged in, he was afraid they could not be so hearty in their commendation of some of the smaller works which the Council, in common with other such bodies, sometimes undertook. The tendency to be universal providers extended to all Government establishments, and even the great railway companies showed a desire to possess departments which would furnish all their requirements. While this tendency had certain advantages, there existed many drawbacks, the principal of which would appear to be the narrowing of the sources of production, and as an outcome of this effect the checking of the spirit of invention and development. In conclusion, Mr. Kaye Gray alluded to the steam-turbine and the high-speed steam-engines as being essentially the outcome of electrical engineering. He advocated the general improvement in our educational methods, but at the same time individualism was required in education as in other matters. It was this individualism which had raised the country to its present position, and he did not think we were yet so decrepit as to require artificial barriers for our protection.

Mr. JAMES SWINBURNE proposed the toast of "Railways and Telegraphs." He said there was no doubt in the minds of the members that it was the right thing to electrify every railway forthwith. Unfortunately, the aid of Parliament had to be sought, and this resulted in great and interested opposition. He thought that these large companies should have the power to develop and improve without restrictions which tend to render profitable working impossible. With respect to the telegraphs, our interests were enormous, and he looked to telephones to solve the traffic problem which Sir John Wolfe Barry was engaged upon. He gathered that the enquiry had shown ordinary methods to be quite useless, as if the facilities of transport were doubled four times as many people tried to travel. A telephone system that would work would save the situation.

Sir C. J. OWEN replied for the railways, and acknowledged the service which electricity now rendered. He hoped that with legislative restrictions removed, an even closer alliance between railways and electrical engineering would be for the commcn good.

Sir JOHN WOLFE BARRY, replying for telegraphs, said the country should be proud of having led the way in submarine telegraphy, because it still held the predominating interest in such undertakings. He gave statistics of these cable enterprises and of the great reduction in rates—*i.e.*, from 60 to 70 per cent.—which have been made during comparatively recent years. The average charge for telegraphing 100 nautical miles was only ½d. per word, or only double the charge on land lines, which cost so very much less to construct. With respect to wireless telegraphy, he took a great interest in the same, and thought the facts were not always appreciated. His company had five cables from Cornwall, which at busy times dealt with 15,000 words an hour. Forty cables touched English soil, and at the same rate it meant 120,000 words an hour, or 2,000 a minute, equal to 12,000 letters a minute. Fancy that discharge of letters bombarded into the ether and encountering an equal bombardment from foreign countries! It was an appalling prospect, and any attempts at tuning would encounter tremendous difficulties and complications.

Prof. S. P. THOMPSON then proposed "Our Guests," to which toast Lord CLAUD HAMILTON, Sir WILLIAM WHITE, and M. E. HOSPITALIER replied. The last-named received a great ovation.

FIREPROOF CABLES.

A speciality in the way of cables which will, no doubt, find wide favour has recently been introduced by Messrs. W. T. Glover and Co., Limited, Manchester. We refer, as the headline indicates, to the firm's fireproof type of cable. The need for such a cable has been increasingly felt of late, especially in some of the newer fields of electrical enterprise—mining and railway work, for instance. Nor will it lack employment in connection with older-established branches of electrical work. Behind switchboards, and for arc lamp leads, theatrical displays, temporary installations, etc., fireproof cables should find a large field of employment awaiting them.

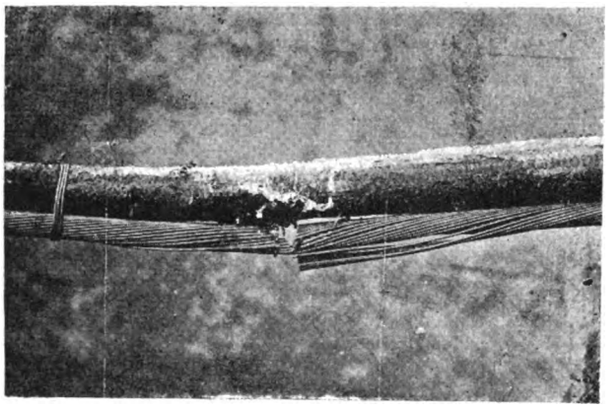
Glover's Fireproof Leather-Braided Cable.

The following is a description of the general method of manufacture: The cable is insulated with pure and vulcanised rubber and served with proof tape in the ordinary way. It is then passed through a bath of the patent fireproof solution, and a braiding of tanned jute, which has been treated with this solution, is then put over this. After braiding the cable passes through another bath of the solution, which completes the operation. If further protection is required, another braiding of leather thongs is put over all, the whole making a thoroughly well-insulated and strong mechanical job (see illustration herewith). For cases where cables already installed require protection from fire, Messrs. Glover make a fireproof tape which can be lapped over these cables and will answer the purpose. This doubtless will be of considerable use in those risky situations where an arc would play havoc with the well-dried braids and tapings that are still to be found behind switchboards all over the country.

The following are some particulars of tests made upon these cables by a very prominent firm largely interested in electrical railway work, to satisfy the Board of Trade as to the use of the same in connection with a large railway scheme. A length of ordinary $^{0}1/_{13}$ rubber cable which was being made in the works was taken, the fireproof coverings of which consisted of three braids of asbestos and three braids of fireproofed tanned jute. A piece of bare copper strand was fastened to the outside of this cable, and the cable and bare strand were connected to the terminals of the generator, capable of giving 1,200 amperes at 500 volts. Half a dozen punctures were made in the coverings of the insulated fireproof cable, and a short-circuit was made by a piece of copper wire from the conductor thus exposed to the bare strand outside with the object of starting the arc. It was found that an arc of 700 or 800 amperes could not be maintained owing to the rapid carbonising effect of such a heavy current. The

Digitized by Google

largest current which could be permanently kept on for 10 or 15 minutes was, roughly, from 150 to 200 amperes. This current did not give a steady blazing arc, but sparked about the faulty places generally. This condition was kept up for 12½ minutes. Ultimately the current increased very suddenly to 1,500 amperes or more, when the circuit breaker operated. The application of the current to the faulty spot was repeated five times, but the time during which it was possible to maintain an arc varied from a few seconds to a few minutes before the maximum current passed, operating the circuit breaker. The same terrific arc and blazing flash took place each time, and the final state of the cable is shown on the photo reproduced herewith, which was taken within 20 seconds of the last application of the current. The absence of smoke or smouldering of the fireproof coverings is clearly shown in the photograph, and this is in spite of the fact that the experiments were made in the open air with a fairly strong wind blowing.



Glover's Fireproof Cable, showing effects of short-circuiting test.

Fuller details and samples, we understand, may be obtained by applying to Messrs. Glover direct.

TRADE NOTICES AND NOVELTIES.

"Ediswan" Specialties.

CELL-TESTING INSTRUMENTS (Leaflet No. I, 2,018).—This comprises a new line of small portable ammeters and voltmeters for stationary and portable accumulators; they are also specially suitable for motorcar batteries. The larger ones are made in both round and square cases, the former being of polished brass, the latter of cast aluminium. The terminals have a special device which makes it impossible for the milled nuts to come off. Both instruments can be supplied either as ammeters or voltmeters. A watch type of voltmeter, with flexible cord and two contacts, is also listed; this is also suitable for ignition cells, etc. It is put up in gunmetal case with silvered dial. All these instruments are made at the works at Ponder's End, and whilst the price is on competitive lines, the workmanship and finish are of the highest.

CONTINUOUS-CURRENT "LILIPUT" ARC LAMP (Leaflet No. H, 2,019).—Describes the "Liliput" arc lamp with accessories. This lamp is too well known to necessitate a special description.

IMPROVED RADIATOR LAMPS (Leaflet No. L, 2,021).—During past years it has been a frequent complaint of the people using electric glow radiators that they could not obtain spare lamps. The "Ediswan" Company have taken steps to see that this need not occur again, and this leaflet illustrates the new and improved "Royal Ediswan" radiator lamp. An oval window has been introduced into the obscured glass, through which the filaments can be inspected. In addition, an improved and ventilated flanged cap is provided and secured by hard cement. This ensures better fixing of the cap. The filaments are prepared by a very special process, giving increased strength.

THREE-PLATE PATTERN H.V. CEILING ROSE (Leaflet No. A, 2,022).—In order to avoid the necessity of having so many "points" in such places as offices, factories, etc., where appearance is not a *sine quâ non*, the Ediswan Company introduced their three-plate pattern H.V. ceiling rose, by means of which two or more flexible pendants may be controlled by more than one switch. The special porcelain bridge separates the terminals from each other, and secures absolute immunity from short-circuit, whilst relieving the terminals from all strain.

THE CHOICE OF THE ROTOR DIAMETER OF INDUCTION MOTORS.*

In the design of induction motors the mistake is often made of choosing a very large diameter for the rotor with a view to obtaining a good power factor. Since, however, the length of the end connections, and, therefore, their inductance, is increased by this means, it may often happen that the desired result is not obtained, and that, in spite of the increased cost of manufacture, the power factor may be actually lowered.

In the following article the writer wishes, in the first place, to emphasise the importance of that part of the total inductance which is due to the end connections,† and, in the second place, to develop a simple and practical method by which the best dimensions may be decided.

On p. 36 of Behrend's excellent treatise‡ on induction motors, the following formula for calculating σ is given:

$$\sigma = C\frac{\Delta}{t},$$

where C is a figure which is dependent on the slot dimensions and other conditions, Δ is the length of air-gap, and t the pole pitch. Behrend estimates that C varies between 10 and 15 for half-closed slots. This formula is extremely useful on account of its simplicity, especially if experimental results are available by which to decide the value of C.

The present writer has attempted to estimate the leakage flux of induction motors by a method analogous to that which has been found satisfactory in determining the reactance voltages of continuous-current machines. Table I. has been obtained in this way, and is in fair agreement with test results.

TABLE I.

Pole pitch in centimetres.	Flux per 1 cm. length of winding embedded in iron, per ampere-turn, in C.G.S. lines.		
	Open slots.	Half-closed slots.	Completely closed slots.
20	·86	1·04	1·24
25	·69	·83	1·0
30	·57	·69	·83
35	·49	·59	·71
40	·43	·52	·62
45	·38	·46	·55

It will be seen that the number of magnetic lines per 1cm. length of winding in iron and per ampere-turn has been taken as inversely proportional to the pole pitch. The flux per 1cm. of end length may be taken as ·4 for all values of pole pitch. Naturally, considerable variations from this may occur with different mechanical arrangements of the end connections. For motors having squirrel-cage rotors ·3 C.G.S. lines per ampere-turn per 1cm. of end length should be used, and the total should be estimated on the basis of the length of the stator end connections. The predetermination of the inductance of induction motors is carried out in the same way as the determination of the magnetising current, but whilst for the latter the magnetic circuit looped with the secondary winding alone is considered, all the remaining magnetic circuits are taken into account when calculating the inductance.

Compared with the short-circuited coils of a continuous-current machine the leakage paths are much more restricted, and this explains why the figures in Table I. are so much lower than those employed for the calculation of the reactance of continuous-current machines. For the latter an average value of 4 C.G.S. lines per ampere-turn per 1cm. of embedded length and ·8 C.G.S. lines per ampere turn per 1cm. of free (or end) length have been found satisfactory. The conductors per pole and phase are also much more spread out in the case of induction motors than in con-

* Translation of an article by H. M. Hobart in *Elektrotechnische Zeitschrift* for Nov. 12, 1903.

† This has long been known, and has been pointed out by several designers. (See M. Breslauer's criticism of Behrend's treatment in *Elektrotechnische Zeitschrift*, 1903, No. 24). It is doubtful, however, whether the effect has been estimated at so high a figure as in the motor given as an example in this article.

‡ "The Induction Motor," New York *Electrical World and Engineer*, 1901.

Digitized by Google

tinuous-current machines. Since the pole-pitch in the former varies between 18cm. and 45cm., the conductors of each coil side take up from 6cm to 15cm., and this in great measure accounts for the low values in Table I.

An example of the estimation of σ is worked out below in order to show the application of the method. Diameter of rotor, 102cm.; periphery of rotor, 320cm.; number of poles, eight; pole pitch, 40cm. The slots are approximately three quarters open, and therefore the values chosen are ·44 C.G.S. lines per ampere-turn per 1cm. of embedded length, and ·4 C.G.S. per ampere-turn per 1cm. of free length.

Effective length of core parallel to spindle = 25·4cm.
Average length of one stator turn = 181cm.
Length of one turn embedded in iron = 51cm.
Free length of one turn = 130cm.
C.G.S. lines per ampere-turn of embedded length = 51 × ·44 = 22.
C.G.S. lines per ampere-turn of free length = 130 × 4 – 52.*
C.G S. lines per ampere-turn = 74.
Number of stator slots = 120.
Number of stator slots per pole and phase = 5.
Conductors per slot = 4.
Turns per pole and phase = 10.
(In reality there is one coil of 20 turns per pair of poles, and not one coil of 10 turns per pole.)
Leakage flux per coil per ampere = 74 × 20 = 1,480.
Inductance per coil = 20 × 1,480 × 10^{-8} = ·000296 henry.
Inductance per phase = ·000296 × 4 = ·00118 henry.
Periods per second = 40.
Reactance per phase = 6·28 × 40 × ·00118 = ·296 ohm.

The motor is built for a terminal voltage of 550, and as the stator winding is star coupled the voltage per phase is $\frac{550}{\sqrt{3}}$ = 318 volts. The short-circuit current at normal terminal voltage will then be

$$\frac{\text{terminal volts per phase}}{2 \times \text{reactance per phase}} = \frac{318}{2 \times \cdot 296} = 536 \text{ amperes } (= A).$$

Calculation of the magnetising current:

Primary terminal voltage (= E) = 318.
Turns in series per phase (= T) = 80.
Periodicity per second = 40.
Total flux per pole (E = 4·2 T N M × 10^{-8}) M = 2·37 × 10^{6}.
Length of iron core (= λ) = 25 4cm.
Diameter of rotor = 102cm.
Pole pitch (= t) = 40·2cm.
Breadth of (slot + tooth) for stator = 2·68cm.
Breadth of (slot + tooth) for rotor = 2·23cm.
Stator slot opening = ·9cm.
Rotor slot opening = 8cm.
Part of stator surface composed of iron = 66 per cent.
Part of rotor surface composed of iron = 64 per cent.
Average surface composed of iron (= p) = 65 per cent.
Average section of air-gap per pole (= $\lambda \times t \times p$) = 660 square centimetres.
Factor to allow for fringing, 1·2.
True section of air-gap per pole, 790 square centimetres.
Average air-gap density, 3,000.
Maximum air-gap density (= 1·7 times the average density) = 5,100.
Air-gap length, ·32cm.
Air-gap length (including allowance for tooth saturation) = ·35cm.
Ampere-turns per pole, 1,430.
Ampere-turns per pole and phase, 715.
Turns per pole and phase, 10.
Maximum current per phase, 71 5 amperes.
Effective magnetising current per phase = 50 amperes (= B).
Diameter of the Heyland circle = A – B = 486 amperes.

$$\sigma = \frac{B}{A - B} = \frac{50}{486} = 103.$$

$$\cos \phi = \cdot 83.$$

It is clear that Behrend's formula was based on the assumption that the inductance was directly proportional to the iron length.* The above method, which takes the effect of the end length into account, shows, however, that the inductance of only that portion of the winding which is embedded is proportional to the iron length. The inductance of the free length is directly proportional to the pole-pitch, so that the total inductance falls off much less rapidly with increasing pole-pitch than would be expected from Behrend's formula, and it may even increase with increasing pole-pitch. Nevertheless, Behrend's simple formula forms a quicker and more satisfactory method for predetermining σ than the method based on the calculation of the flux per ampere-turn per 1cm. of embedded length and free length respectively.† It is only necessary to determine suitable values for the constant C, and those given in Table II. are in close agreement with the figures in Table I.

TABLE II.

Ratio of effective core length to pole pitch in percentages.	Value for C in Behrend's formula: $\sigma = C \frac{\Delta}{t}$	
	Open slots.	Completely closed slots.

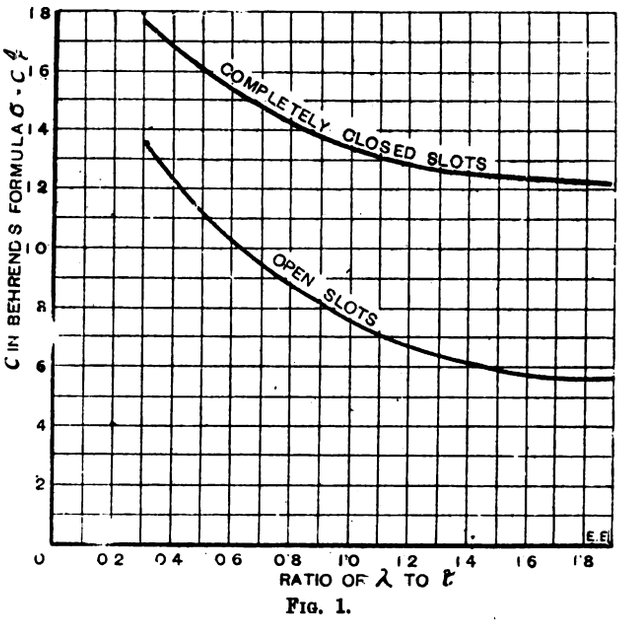

FIG. 1.

These results have been put into curve form in Fig. 1, and form a good basis for the calculation of σ.

A CENTRAL TECHNICAL COLLEGE PUBLICATION.

Many old students of the Central Technical College will be interested to learn of the publication of a new magazine

* This example shows the great importance of the end connections. A much better motor as regards power factor would have been obtained if the diameter had been made smaller and the coil length greater.

* It would seem as if the simplest formula in which the facts can be embodied is

$$\sigma = K \frac{\Delta (\Delta + K_1)}{t^2},$$

where K and K_1 are constants which are proportional to the ratio of $\frac{\lambda}{t}$ and to the slot depth respectively. It is, however, preferable to keep the formula as simple as possible, so that the writer thinks it better to retain Behrend's original formula, together with the values of C got from Table I. and Fig. 1.

† Though this method gives a better insight into the relative effects of embedded and free length.

Digitized by Google

which has been brought out under the auspices of the Central Technical College Old Students' Association. Its comprehensive title is "The Central," and it has as editors Prof. E. Frankland Armstrong and Mr. Maurice Solomon. The laudable object of the magazine is to keep old students, whether on the banks of the Nile or on the plains of India, in touch with what is doing at the college and in the laboratories in which they spent their early days—in a word, it is to be a journal devoted to the maintenance and spreading of the interests of the college. The first number which has reached us is well calculated to give a good impression. Its get-up is in the best style, and the reading matter is of the highest standard. An excellent portrait of Prof. W. C. Unwin is presented as a frontispiece, and among the principal contents is an article on some research work of the past session, and another on the special work of an Old Centralian by Mr. W. Duddell, to be followed by others of a similar kind on the work which other old students are doing. The new electrical laboratories at the college are described, and some excellent illustrations lend a special interest to the subjects discussed. At first the magazine will be published two or three times a year, and more often later on should this be justified by the demand.

WALLASEY MUNICIPAL TRAMWAYS.

Mr. R. R. Greene, general manager of the above undertaking, has presented his report to the chairman and members of the Tramways Committee for the year ending March 31 last. The report states that on March 17, 1902, the first service of electric cars was commenced on the Rake-lane route, and on the 19th of the same month the cars started to run on the Sea Bank-road route. To meet the requirements of workmen and others desirous of reaching Liverpool in the early morning, a service of cars was also established from Molyneux-drive and Wallasey-road. These cars are much appreciated, and show satisfactory financial results. The Warren-drive route was opened on May 17, 1902. The suite of offices which the committee decided to erect in Sea View-road for the accommodation of the staff has been completed, and has proved well adapted for the purposes intended. A successful benefit society was established in July, 1902, by and for the employés, who elect their own committee, and the management is solely in their own hands. For a small weekly contribution a payment is made to members during sickness, and a funeral allowance is also provided by the society for the burial of deceased members. The efficiency of the lifeguard adopted by the committee and fitted on the cars has been proved on at least two occasions, when children who ran in front of the cars and were knocked down would have been seriously injured, if not killed, but for having been picked up by the guard. The comparative immunity from serious accidents during the year is matter for congratulation, and may fairly be taken as evidence of the care and vigilance exercised by the members of the traffic staff in the performance of their respective duties. The rolling-stock at present in use consists of 30 double-deck cars mounted on Brill single trucks driven by two motors of 25 h.p. each, seating accommodation being provided for 22 passengers inside and 34 outside. One of these cars has been fitted with a top covering, and four others are being similarly fitted; also one combined track cleaner, watering-car, and snow-plough on Brill single truck driven by two motors of 25 h.p. each.

Attached we give an abstract of the accounts for the year. The total expenditure on capital account on March 31 was £120,503.

Cr. Revenue Account No. 1.	£	s.	d.
Traffic receipts	30,907	3	8
Advertising rents	455	7	9

Balance, March 31, 1903	2,806	18	6
	£8,088	7	3

Following we give a statement showing the electrical energy consumed, miles run, passengers carried, and receipts during the year: energy in Board of Trade units, 979,133; miles run, 654,742·390; passengers carried, 5,685,182; receipts, £30,907. 3s. 8d. Average per car mile: Board of Trade units, 1·49; passengers, 8·68; receipts, 11·33d.

PERSONAL.

Mr. Standen Leonard Pearce was on Wednesday appointed to succeed Mr. G. F. Metzger in the position of chief engineer to the electricity department of the Manchester Corporation. Mr. Pearce is at present deputy chief electrical engineer. The appointment will begin on Feb. 1 next, on which date Mr. Metzger will take up the position of consultant engineer, which position he will keep until his extension scheme has been completed. Mr. Metzger's salary is £900. Mr. Pearce is to have £800 a year, the same that his predecessor had to begin with. His present salary is £500 a year. The committee have decided to appoint an assistant electrical engineer at a commencing salary of £250 per annum. The *Manchester Guardian* says: "Mr. Pearce is a son of the late Rev. Standen Pearce, Baptist minister, and was born at Crewkerne, Somerset, in 1872. Although young, he has had a very varied experience of electrical work for 15 years. After education at Bishop's Stortford College, he was apprenticed in 1888 to Messrs. J. G. Statter and Co., West Drayton, electrical and mechanical engineers. His identures were for four years, but at the end of two years the firm gave up business. Mr. Pearce then joined himself to Messrs. Thomas Richardson and Sons, Hartlepool, marine and electrical engineers. He remained with this firm for over four years, spending 3½ years in the various workshops and a year in the drawing and scientific office as a draughtsman. In this way Mr. Pearce gained a practical knowledge of mechanical engineering work, especially as it affects electricity. Desiring to gain further practical acquaintance with machinery, he entered the service of the British India Steam Navigation Company, London, and for two years, on various vessels, had complete charge of a 'watch,' having control of all the main and auxiliary electrical and hydraulic machinery with which all modern ships are equipped. In 1896 Mr. Pearce became assistant engineer with the Metropolitan Electric Supply Company, London. With that firm he remained till 1899, and when he left he was chief assistant engineer. From the Metropolitan he went for a year or so to the British Thomson-Houston Company, London. Thence he passed to the Central London Railway Company, and became superintendent engineer at the power station. He was in the company's service during the construction of the 'Twopenny Tube,' as the London electrical railway has been called. In March, 1901, Mr. Pearce came to Manchester, having been appointed deputy chief electrical engineer to the Corporation."

Mr. L. B. Hogarth, assistant engineer Sculcoates lane electric light and power station, Hull, has been appointed assistant engineer to the Ebbw Vale Steel, Iron, and Coal Company, Limited.

Mr. Thomas Mason, I.S.O., telegraph traffic manager at St. Martin's-le-Grand, retires at the end of the year. He will be best remembered as superintendent of the special staff, a position which he held for 30 years, during which the telegraphing of the most important events and speeches in the United Kingdom was effected under his control. In acknowledgment of his long and meritorious service the King in March last personally conferred on him the insignia of a Companion of the Imperial Service Order.

Mr. J. B. Hudson, the senior assistant at the Bootle electricity works, has been appointed to act as deputy electrical engineer during the absence of the electrical engineer, and Mr. E. W. King has been appointed assistant electrical engineer at the salary of £110 per annum, rising by annual increments of £10 to £150 per annum.

Mr. Grimsdale, the electrical engineer at Warrington, has resigned.

Mr. J. R. Williams, A.M.I.M.E., A.M.I.E.E., A.I.N.A., of Sheffield, has been elected a Fellow of the Society of Arts.

APPOINTMENTS VACANT.

Assistant Electrical Engineer, Sanitary Commissioners Gibraltar. Salary, £200 per annum. Applications by Dec. 16. See advertisement in former issue.

Traveller with connection amongst buyers of arc lamps and switchboards, Box 808, *Electrical Engineer* Office.

Surveyor and Electrical Engineer, Boston. Salary, £300. Dec. 18.

Switchboard Attendant, Motherwell. Salary, 25s. per week.

Shift Engineer, Fulham. Salary, £104 per annum. Dec. 12. See advertisement in last issue.

Clerk and Accountant, Portsmouth Telephone Department Salary, £90 per annum. Dec. 14. See advertisement in last issue.

Wireman, at the Goldsmiths' Institute, New Cross, to conduct classes in electric wiring. See advertisement.

PHYSICAL SOCIETY.

At the meeting of the society on Nov. 27, Dr. R. T. Glazebrook (president), in the chair,

Mr. Horace Darwin exhibited an electric thermostat. The thermostat shown at the meeting was made for Lord Berkeley, and is similar to one made for the spectograph of the 24in. refractor of the Royal Observatory, Cape of Good Hope. The vessel, the temperature of which is to be maintained constant, is surrounded by oil contained in a bath. In the oil are placed two heating coils, through which electric currents pass. By automatically controlling these currents the temperature of the oil, and consequently of the inner vessel, is kept very nearly constant. The control is effected by means of a Wheatstone bridge in the outer oil bath. This bridge has two opposite arms of copper and two of manganin, so that it is only balanced at some definite temperature. Its deviations from balance affect the position of a long horizontal boom attached to the suspended coil of a galvanometer. The position of the boom determines the greater or less descent of a "hit-or-miss" arm which is periodically raised by a rotating cam, and can only fall to its lowest position when the galvanometer boom is to one side and allows it to pass; this position of the boom corresponds to a fall of temperature of the controlling bridge. Thus the position of the "hit-or-miss" arm at its lowest position depends on the temperature, and it is the variation of this position which regulates the amount of current passing through the heating coils. When the "hit-or-miss" arm is at its highest position the galvanometer boom is absolutely free to move to its position of equilibrium. We may call the two coils the intermittent and the permanent heating coils. At every rotation of the cam the "hit-or-miss" arm is lowered, and if it passes the galvanometer boom a key is closed and a current passes through the intermittent heating coil. Thus the frequency of the intermittent current depends on the temperature of the oil-bath. The duration of the time that the key is closed also varies, it may be long or very short. Every time the key is closed a movement takes place which increases the duration of the next closure of the key. The arrangement of the mechanism is such that when the temperature is steady the "hit-or-miss" arm will pass the galvanometer boom as many times as it is stopped by it in a given time. The current passing through the permanent heating coil is also automatically regulated: if there is not enough heat passing into the oil, this current is gradually increased. This is done by cutting out resistance coils which are in series with the permanent heating coils. The cam which moves the "hit-or-miss" arm is driven by a worm-gear and any suitable motor, and the oil is kept thoroughly stirred by a fan.

Mr. W. C. D. Whetham asked what accuracy was aimed at in the instrument?

Mr. A. P. Trotter said that the use of thermostats would become more and more important with the perfection of thermometers. It was possible to keep a temperature constant within $\frac{1}{100}$deg. C., but it was very difficult to determine the temperature to that degree of accuracy. In high-class resistance measurements with a Carey Foster bridge one of the greatest difficulties was with regard to the temperature, which must not only be constant but also capable of exact determination. In the constant temperature room at the Board of Trade standardising laboratory the temperature varied by less than $\frac{1}{4}$deg. C. from day to day, and he would like to know the greatest accuracy obtainable with ordinary devices in such a room before considering the introduction of the complicated instrument shown to the meeting.

The **Chairman** expressed his interest in the author's communication, and said he had recently been trying to solve a somewhat similar problem by making use of a horizontal boom, attached to the suspended coil of a galvanometer, for making and breaking a current. His object was to regulate a current of the order of 50 amperes. Dr. Glazebrook asked if it was desirable or important to utilise all the adjustments in the instrument.

The **Author**, replying to Mr. Whetham, said the instrument had been made as sensitive as possible, but he was not aware within what limits it would maintain the temperature of the bath. The thermostat supplied to the Cape Observatory was capable of keeping the temperature within $\frac{1}{100}$deg. C. for a period of eight hours. In reply to the Chairman, he said that when working with small variations of the external temperature it might be possible to dispense with one or other of the adjustments; but when the external variations were large it was necessary at times to supply a large quantity of heat to the oil-bath, and in order to do this effectually he thought all the adjustments of the instrument were desirable.

A paper **"On the Occurrence of Cavitation in Lubrication"** was read by **Mr. S. Skinner.** The experiments described in the paper arose from an observation made when determining the refractive index of a liquid by means of Newton's rings. As Newton showed, the rings can be obtained when a liquid is run into the space between the lenses. If, when the liquid has been introduced, the upper lens be rolled on the lower, the observer sees following the central dark spot a crescent-shaped space, very bright provided the illumination be sufficiently oblique. This is a vacuous or vapour-filled space, for when the motion of rolling ceases the liquid flows into the space and completely fills it. The inflow of the liquid depends in some way on the viscosity, and the effects are more pronounced when a more viscous liquid is used. The most convenient mode of observation is to use a deeply-coloured liquid, and to look at the space by transmitted light. The author has found that a convenient liquid is a strong solution of fuchsin in glycerine. This red solution is so deeply coloured that, even up to the point where the lenses are nearest, some colour shows, and light is only brightly transmitted at the place where there is a break in the liquid. The cavities which are formed must be produced either by splitting the liquid itself, or by tearing the liquid from the glass surface. The effect may be described as a case of "cavitation." Some experiments were made to imitate the actual case of a fully lubricated axle rotating under a bearing. For this purpose, a thick disc with its edge worked to a spherical surface of curvature equal to the radius of the disc, mounted on an axle, was arranged so that the lower part of the disc dipped into an oil-bath, whilst a flat plate of glass rested on the upper edge of the disc. As the disc rotated oil was carried round, so that the point of contact of the disc and plate was maintained copiously lubricated. The disc represented the axle and the plate the bearing on it. What happened on rotation could be observed by looking through the glass plate with a magnifying glass. It was seen that during motion a cavity was formed on the side where the edge of the disc was moving away from the plate. The size of the cavity depended on the rate of rotation. In ball-bearings completely immersed in oil, the experiments show that there must be a small cavity near the point of nearest approach of each ball to its neighbours, and also to the surface on which it is running. As the friction of the bearing is the viscous friction of the oil, it follows that the friction must be considerably reduced by the formation of these cavities, which are filled with relatively non-viscous vapour. The high lubricating property of oils owes its origin not only to their superior viscosity, but also, possibly, to the facility with which cavities may be formed in them.

The author illustrated his paper by a series of experiments showing cavitation produced by rolling lenses on plates.

Prof. J. D. Everett said it was interesting to note that cavitation had been observed and correctly explained by Newton. He (Prof. Everett) mentioned that a similar phenomenon was exhibited by a steam-roller working on mud, and gave an explanation of the production of pressure and tension respectively in the liquid near the contact of the roller and the mud. If the mud were sufficiently viscid, cavitation might occur behind the roller.

Mr. W. A. Price said that the observations of the author could not fail to be of interest to engineers. He asked to what extent cavitation was going on in an ordinary round bearing or in the slide valve of a locomotive, and suggested that the views of engineers upon the subject of lubrication might require considerable modification in the light of the present paper.

Mr. C. V. Boys expressed his interest in the paper and the experiments shown by the author. He said that, like Mr. Price, he had been thinking of the influence of cavitation upon machine bearings, but, unlike him, he had not come to the conclusion that our ideas on the subject should be changed. In the author's experiments cavitation was produced by the approach of two surfaces on one side of their line of contact and their recession on the other side. In the case of a cylindrical bearing the space between the shaft and journal was believed to be completely filled with oil, and if the shaft were truly concentric there would be neither approach nor recession. He thought that in the case of any cylindrical bearing, the rate of approach and recession would never be great enough to produce cavitation. The case of ball-bearings, when using a thick lubricant, was different, and cavitation might occur. If it did, it would occur behind the point of contact, and although the production of cavitation involved a loss of energy he questioned whether it did any appreciable harm. Mr. Boys referred to the dendritic patterns formed, when mixing paints, by lifting the muller from the plate, and suggested that their formation was a phenomenon of the same kind as cavitation.

Mr. R. Appleyard said there were two distinct cases to be considered: (1) a wheel on a plane, and (2) a shaft in its bearing. He agreed with Mr. Boys that the cavitation occurred behind the point o contact and did not matter in the case of a ball-bearing. But if cavitation occurred in a cylindrical bearing, the cavity would form between the two surfaces which were next coming into contact. If the surfaces were smooth little harm would ensue, but if they were rough the occurrence of cavitation would be detrimental, for it would result in direct contact.

Dr. A. Griffiths asked the author if cavitation in lubrication was supposed to be an advantage or a disadvantage.

Mr. Skinner, replying to Mr. Boys, suggested the construction of glass bearings to determine whether cavitation occurred in cylindrical shafts. He thought that cavitation in lubrication was an advantage as a rule, because spaces formerly filled with viscous material were then filled with something with small viscosity.

Prof. R. Threlfall then exhibited and described the following instruments which he has used in the testing of electric generators by air calorimetry: (1) A "hot-wire voltmeter" accurate to $\frac{1}{10}$ volt. The wire in this instrument is very fine, and special precautions are taken to keep the tension on it constant, so that the elongation measured is due only to the expansion of the wire caused by the heating effect of the current. (2) A "Pitot tube" for the measurement of air velocity, the velocity being proportional to the square root of the pressure produced in the tube. (3) A "manometer" for determining pressure differences in Pitot tubes with accuracy. This consists essentially of two bottles containing coloured water, which are connected by a siphon, and the air-space of each bottle is put in communication with its appropriate tube. The readings are taken by setting a pair of needle points just to touch the liquid surface, and then measuring how they differ in level by micrometer screws, or by callipering suitable jaws. The instrument is reliable to 0·01mm. of water pressure. (4) A multiplying pressure gauge, in which the motion of a float or ball is used to operate a finger moving round a dial. The dial is divided in such a manner that the square roots of the pressure differences are read off. Air velocities are therefore given directly.

Mr. Duddell, referring to the voltmeter exhibited, asked if there was any trouble with regard to the temperature variation of the resistance of the wire. In using the instrument with large alternating currents it was necessary to use a standard shunt, and difficulties then arose because of the fact that the self-induction of a shunt, formed of straight bars and capable of carrying the necessary current, was comparable with its resistance. It might be possible to get a satisfactory

Digitized by Google

shunt by doubling the bars upon themselves to reduce the self-induction.

Prof. Threlfall said that there was no difficulty with regard to changes in temperature of the room, because they only altered the zero of the instrument. Referring to the possibility of constructing a low-resistance standard shunt, he said he had calculated the self-induction of the bars forming his shunts, and had come to the conclusion that it was negligible in his experiments. Experimentally he had found that it could not produce an error of 1 per cent. It might be possible to so design a shunt that the mutual induction of its parts would balance the self-induction to a certain extent.

LONDON TRAFFIC ENQUIRY.

The Royal Commission on London Locomotion sat again on Thursday and Friday last week at the Westminster Palace Hotel, Sir David Barbour in the chair.

Mr. Arthur Harrison, borough engineer and surveyor of Southwark, said that the danger arising from costermongers' stalls in the streets was enhanced in the roads along which the electric tramways of the London County Council ran. He urged that the control of the streets by borough councils should not be reduced, but increased, and extra powers should also be given with regard to the opening of trenches, etc. He though the appointment of a board of locomotion was desirable On the question of the veto on tramways, the witness was of opinion that that should be retained by the borough councils. It would be utilised by them with great care.

Lord Ribblesdale: Do you object to having the veto removed because it would deprive you of the power of bargaining which you at present possess?—No, I do not think a bargain has been made with a company, but the veto gives us the power to say that a tramway must be made in such a way as to provide for other traffic.

Mr. R. M. Prescott, town clerk of the borough of Fulham, having given evidence,

Mr. Norman Scorgie, borough engineer and surveyor of the borough of Hackney, gave some interesting figures with regard to the breaking up of roads. In the two years ended Sept. 30, 1903, the Gaslight and Coke Company made 5,981 openings in the street, disturbing 81,773 square feet; the East London Water Company, 2,347 openings, covering 35,880 square feet; the New River Company, 1,833 openings, covering 34,236 square feet; and the Borough Council, including a few by the Post Office Telegraphs Department and the London County Council, 1,113 openings, covering 29,710 square feet. The companies should be required, except in cases of emergency, to obtain the consent of the borough councils before making street openings. The controlling power of the borough council should extend over all bodies having authority to open streets, including the London County Council. No curtailment of the powers of veto over tramway schemes was desirable. Only in one instance had the Hackney Borough Council thought fit to refuse consent. There was an absolute necessity for increased means of communication between the City and the North-East of London. Schemes such as that promoted by the City and North-East Suburban Railway would meet the want. The proposed line to Chequers-green would afford speedy access to the City, and the north-east branch to Waltham would provide for the districts around Victoria Park and Hackney Wick. He was directed by his Council to urge that powers should be given to construct such lines without delay.

Councillor Levy, of the Hammersmith Borough Council, gave evidence on behalf of that body. He stated that there was considerable congestion of traffic, both vehicular and pedestrian, in Uxbridge-road, due to the fact that the termini of the Tube Railway and the electric tramways were at the same point. The widening of Hammersmith-broadway was provided for in the London County Council's Tramways Act, 1903, and when effected it would doubtless afford relief under present conditions, but should any of the contemplated tube railways to Piccadilly be constructed, and the terminal station be placed in the Broadway, as had been suggested, a further widening to provide for the increased pedestrian traffic created thereby might be necessary, in which case the promoters of the railway should be required to bear the cost thereof. The congestion in Uxbridge-road might possibly be relieved by a rearrangement of the tramway terminus, and the pedestrian traffic would undoubtedly be lessened by the extension of the Central London Railway in a half-circle to near Hammersmith-broadway, with a station at an intermediate point at the end. An underground electric railway was much needed between Hammersmith and the City, *via* Kensington, Knightsbridge, Piccadilly, and Charing Cross; also a direct and improved service from Hammersmith Station of the North and South-Western Junction Railway to stations on the North London Railway and to the City, and an improved service to Waterloo, Ludgate-hill, and Clapham Junction on the London and South-Western Railway. At the present time both services were infrequent.

Mr. J. Patten Barber, borough engineer of Islington, gave similar evidence to that of the representatives of other borough councils as to powers of regulating the unloading of barrels and coal, the obstruction of streets due to street markets, and the breaking up streets by statutory companies. Much of the delay and danger now existing in crowded thoroughfares would be prevented by proper widenings and the provision of secondary streets.

Mr. William Eve, alderman of the borough of Stoke Newington, said that he and the Council he represented thought it was absolutely necessary that one authority should have full power of applying to Parliament for powers to construct tramways in London. No well-arranged scheme could be carried out whilst any one borough could prevent, by its veto, an application to Parliament for the construction of a tramway within its area. While any irresponsible person could apply to Parliament for authority even to alter the level of any main thoroughfare or to make a level crossing over it, the London County Council had no power to apply for authority to construct a new tramway unless the road authorities gave their consent. The result was that either good projects had to be abandoned or the London County Council had to consent to onerous conditions to the prejudice of other ratepayers.

The Commission adjourned.

LEGAL INTELLIGENCE.

GREAT NORTHERN AND CITY RAILWAY.

Mr. Justice Wright, sitting in the High Court on Tuesday, disposed of the case of Dawson *v.* the Great Northern and City Railway. The action was originally brought and judgment obtained by the plaintiff at an enquiry held for the purpose of assessing the damage caused to premises in the City-road and stock-in-trade as the result of subsidences consequent upon the construction by the railway company of tunnels for an underground railway; £2,100 was awarded for structural damage and £2,000 for the stock (drapery), and it was agreed that the total amount of £4,100 should be allocated in thirds to the parties interested. The question for the Court now to decide was whether the plaintiff could show title to the amounts which had been ascertained.

His Lordship found for the plaintiff sums amounting to £1,366; but the company having paid £2,000 into court, with a denial of liability, judgment was entered in their favour, with costs.

FERRANTI LIMITED.

On Saturday, in the Chancery Division, Mr. Justice Joyce had before him the action of Poole *v.* Stirling and Ferranti Limited, which came on as a motion for judgment.

Mr. Vernon, for the plaintiff, said the action was brought by debenture stock holders to enforce their security. The defendants (Stirling and Jones) were the trustees for the stockholders, and Parr's Bank were second encumbrancers, they holding a debenture for £30,000, ranking after the debenture stock. Stirling and Jones consented to judgment, and so did the bank, but the company had not put in a defence. The debenture stock, to the amount of £100,000, was issued in November, 1901. The security had not yet become enforceable, and noi nterest was in arrear, but the company was insolvent.

His Lordship made a declaration that the trusts of the debenture stock deed should be carried into effect, and directed the usual accounts and enquiries to be taken.

ALLEGED THEFT OF ELECTRICITY.

At Bow-street Police Court Sir A. de Rutzen heard a charge preferred against George Walter Lawrence, described as an electrical engineer, of stealing electricity to the value of 10s. from Messrs. Coon and Clarke, engravers, of 401, Strand.

Mr. E. Wilmot Seale watched the proceedings on behalf of the Charing Cross and Strand Electricity Supply Corporation.

Detective-Inspector Drew deposed that, in consequence of something which he heard, he went, with Detective-Sergeant Stephens, to 401, Strand, and there saw the prisoner in a top room, which he occupied. An electric lamp was burning in the room, and witness asked him where he got his light from. He replied that he had permission from his landlord to connect the lamp with his wire. The officer told the accused he had information that it was connected with the wire of Messrs. Coon and Clarke, who occupied the floor immediately below, and he admitted that that was true, saying that he did it about two months ago, as he had some bother with his lamp.

On this evidence the prisoner was remanded.

DAMAGES AGAINST THE DUBLIN TRAMWAYS COMPANY.

In the Nisi Prius Court (Dublin) Mr. Justice Madden and a city special jury heard a claim by Josephine O'Brien against the Dublin United Tramways Company to recover damages for injuries sustained by her while riding in one of the defendant company's tramcars on Aug. 23. The plaintiff claimed £1,000 damages. The defendant company denied negligence.

Sir Thomas Myles, ex-president of the Royal College of Surgeons, said the plaintiff was suffering from an internal injury, which he believed was incurable.

Mr. O'Brien, for the defence, admitted that the company were liable, but urged that the damages ought to be moderate.

The jury found for the plaintiff, damages £1,000, and judgment was given accordingly.

A TELEPHONE DISPUTE.

The case of the National Telephone Company *v.* Phelps was mentioned to Mr. Justice Farwell in the Chancery Division on Friday.

Mr. Upjohn, K.C., said an injunction had been granted *ex parte* to be continued until that day, and it was now proposed that it should be continued till the trial. In this case Mr. Phelps claimed the right to disconnect the cable of the National Telephone Company, which served some 66 subscribers, and if that were done considerable public inconvenience might arise.

Mr. Jenkins, K.C., said that the point between his learned friend and himself had been quite clearly defined, and he suggested that the case should be put in the witness list. The only issue was whether the plaintiffs were entitled to maintain a certain cable and any apparatus that might be connected therewith upon certain premises in Southampton-row.

The case was ordered to be set down in the witness list.

COMPANIES' MEETINGS AND REPORTS.

NERNST ELECTRIC LIGHT.

The report of the directors for the year ended Sept. 30, 1903, states that the return of lamps sold in the Company's districts, as well as in England, during the period under review, shows an increase, and the working expenses have been further reduced. As the experimental shops and laboratory have been closed owing to the altered policy of the Company, the directors, acting on the advice of their auditors, have added the sum which previously appeared on the balance-sheet under these headings to the development suspense account, which thus stands at £17,355. As it is clear that a considerable proportion of the above will have to be met before future profits can be distributed, the directors are of opinion that the balance is not available for dividends. The Board consider that the shareholders would be acting wisely in reducing the capital of the Company so that it might represent more accurately the available assets. As already announced, the scheme formulated by a section of the shareholders commends itself to the directors as an equitable basis for distribution between the two classes of shares. The directors regret to announce the retirement of Mr. Hugo Hirst from the Board. Mr. R. J. Wallis-Jones and Mr. A. M. Oppenheimer have been elected as directors.

ISLE OF THANET ELECTRIC TRAMWAYS.

The report of the directors for the year ending Sept. 30 last shows a balance at credit of profit and loss account of £12,304. Traffic receipts amounted to £33,465, as against £35,088 for the corresponding period of last year, a decrease of £1,623, which was entirely due to the inclemency of the weather during the summer and autumn. To pay the debenture interest, dividend on preference shares, interest on loan, fees to debenture trustees and income tax, an additional sum of £3,403 was required, which has been taken from the unappropriated balance at the credit of last year's revenue account. From this balance also a sum of £1,853 has been written off for compensation for accidents, and for other charges in the previous year. These were only ascertained after last year's accounts were closed, and the further sum of £500 has been written off "improvement of cars." The balance of last year's revenue account now stands at £5,047, which is carried forward. The Company has been insured against accidents to third parties since June 16, 1903.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS.

The directors' report for the year ending Sept. 30, 1903, show, after provision for doubtful debts, a net profit for the past 12 months of £54,568. 16s. 3d. Adding £62,361. 11s. 7d. brought forward, and deducting £12,500 interim dividend paid in June, there remains a disposable balance of £104,430. 7s. 10d. The directors recommend the distribution of a dividend of 15s. a share, free of income tax, amounting to £37,500, making, with the interim dividend paid in June, a total payment of 10 per cent. for the year, and leaving £66,930. 7s. 10d. to be carried forward. The general business shows a falling off when compared with last year. To a great extent this is due to the general depression existing in trade, as a result of which competition has been, if anything, keener than usual. The cable to connect San Francisco with the Sandwich Islands, referred to in the last report, was laid for the Commercial Pacific Cable Company by the cable steamer "Silvertown" on Jan. 1 last. The "Dacia" and the "Buccaneer" have been employed in cable repairing work during the year. The works at Silvertown and Persan have been maintained in their usual state of efficiency, and extensions continue to be made. The Company's Act for the amendment of the memorandum of association received the Royal assent on June 30 last. The ground lease for a term of 28½ years of the Cannon-street premises has been purchased. The Company holds a considerable interest in the Palmer Tyre, Limited, and has designed a new motor tyre which attracted a good deal of attention at the recent Stanley Show.

NEW COMPANIES REGISTERED.

Electrophone, Limited.—Capital, £15,000. Object: to acquire and work the undertaking known as Electrophone, Limited.

Derby Electrical Company, Limited.—Capital, £1,000. Object: to acquire and carry on the business of an electrical engineer. Registered office: St. George's Engineering Works, Wood's lane, Derby.

B. B. B. Rubber and Gutta Percha Company, Limited.—Capital, £6,000. Object: to carry on in Great Britain and elsewhere the business of manufacturers of and dealers in rubber and guttapercha goods. Registered office: 8, Church-street, Coatbridge.

White and Hemphill, Limited.—Capital, £10,000. Objects: to acquire the business of William White and Son, of 34, Roxburgh-street, Greenock, and to carry on the business of iron and brass founders, mechanical and electrical engineers, boilermakers, etc. Registered office: 34, Roxburgh-street, Greenock.

Bukit Rajah Rubber Company, Limited (79,314).—Capital, £70,000. Objects: to acquire the estates in the district of Klang, in Selangor, Straits Settlements, known as Bukit Rajah, Sungei Binjai, New Eskdale, Delabole, Bukit Duku, and Booneans; to plant, grow, produce, prepare for market, and deal in indiarubber, guttapercha, etc.

British Johns-Manville Company, Limited (79,272).—Capital, £5,000. Object: to carry on the business of dealers in and importers, exporters, and manufacturers of all kinds of electric, magnetic, galvanic, chemical, and other machinery, apparatus, and appliances, materials, and substances used by electrical and other engineers, etc. Office: 81, Fenchurch-street, E.C.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Preston.—The Corporation invite tenders for a traction switchboard and accessories. Tenders by Dec. 12. See advertisement in former issue.

London, N.—The Hornsey Borough Council invite tenders for the supply of 100 cast-iron lamp columns. Specifications from the Surveyor. Tenders by 14th inst.

Wiring.—The Scottish office of the May-Oatway Fire Appliances, Limited, invite tenders for wiring of buildings for the May-Oatway fire alarms. See advertisement.

Barcelona.—The Harbour Works Commissioners require tenders for installation of electric light and power by Feb. 15. Particulars may be obtained from the Commissioners.

Pontypridd.—The Urban District Council invite tenders for free wiring, and for Section O, the supply of tramcars. Tenders by 24th inst. See advertisement in last issue.

Stockton-on-Tees.—The Corporation invite offers for hiring or hire-purchase system for motors to be fixed on their mains. Tenders by 15th inst. See advertisement in last issue.

Govan.—The Corporation invite tenders for the supply, delivery, and erection of coal bunkers, conveyor, and electric capstan. Tenders by 28th inst. See advertisement in last issue.

Colchester.—Tenders are invited for erection of electrical works at Hythe Causeway, Colchester. Specifications, etc., from Mr. Ernest R. Beckwith, architect, 10, Trinity-street, Colchester.

Stockport.—The Electricity Committee invite tenders for supply of 3in. and 4in. cast-iron mains, and for irregulars from 3in. to 6in. Specifications from the Engineer. Tenders by 16th inst.

Peteringa (Croatia).—The Municipality require tenders for installation and working of electric lighting; 6 to 8 arc and 160 to 180 incandescent lamps are required for the street-lighting.

Greenwich.—The London County Council invite tenders for six electrically-driven three-throw boiler feed pumps. Specifications, etc., at the County Hall, Spring-gardens, S.W. Tenders by Jan. 19.

Plasencia.—The Municipality require tenders for electric lighting of the town for 12 years by 26th inst. Particulars from the above authority, Casas Consistoriales, Plasencia, Province of Carceres, Spain.

London, E.C.—The East Indian Railway Company invite tenders for the supply and delivery of electric plant for a lighting installation. Specifications from Company's Offices. Tenders by 12 noon on 23rd inst.

Hackney.—The Council invite tenders for feeding and distributing mains. Specifications from Mr. Robert Hammond, M.I.C.E., 64, Victoria-street, Westminster, S.W. Tenders by Jan. 4, 1904. See advertisement.

Sydney (N.S.W.).—Tenders are asked for the supply of continuous and alternating current meters. Specifications, conditions, and forms of tender are obtainable from Messrs. Preece and Cardew, 8, Queen Anne's-gate, S.W.

Warrington.—The Electricity Committee invite tenders for the supply of earthenware ducts for the drawing-in system of mains. Specifications from the Electrical Engineer, Howley, Warrington. Tenders by 14th inst.

Camberwell.—The Borough Council invite tenders for the maintenance of electric bells and private telephones. Forms of tender from Mr. W. Oxtoby, borough engineer, Town Hall, Camberwell, S.E. Tenders by 5.30 p.m. on Jan. 18

Bradford.—The Corporation invite tenders for an installation of electric lighting at the new district baths, Drummond-road. Specifications, etc., from City Architect, Whitaker-buildings, Brewery-street. Tenders by 12 noon on 14th inst.

Erith (Kent).—The Urban District Council invite tenders for the execution of all installation work required under their assisted wiring scheme for period ending Dec. 31, 1904. Specifications, etc., from Mr. Geo. E. Heath, electrical engineer. Tenders by 4 p.m. on 14th inst.

Christchurch (New Zealand).—Tenders are invited for the complete installation of electrical tramways, other than buildings. Specifications, etc., may be obtained from the Agent-General for New Zealand, Victoria-street, S.W. Tenders by March 17. See advertisement.

Culiacan (Mexico).—Tenders are invited for lighting the town by electricity: 60 arc lamps of 1,200 c.p. and 110 incandescents of 50, 30, and 16 c.p. will be required. Propositions will be received by letter until Dec. 31 in the Secretaria del Ayuntamiento, Culiacan, where further information may be obtained.

West Ham.—The Education Committee invite tenders for the electric wiring and fittings and for the hot-water heating apparatus required at the Whalebone-lane Higher Elementary School, Stratford, E., and Shipman-road School, Custom House, E., now in course of erection. Tenders by Dec. 14. See advertisement in former issue.

Leicester.—The Gas and Electric Lighting Committee invite tenders for the supply and delivery of the necessary cast-iron pipes

Digitized by Google

and connections, from 2in. to 36in. in diameter, required during 12 months ending Dec. 31, 1904. Specifications from Mr. Alfred Colson, M.I.C E., M.I.E.E., engineer and manager. Tenders by 11 a.m. on 12th inst.

Enniscorthy (Ireland).—The District Lunatic Asylum Committee invite tenders for the following works: generator and motor-generator converter; motor and motor pumps; accumulators; main switchboards; overhead conductors and telephone; gearing and shafting; wiring asylum. Specifications, etc., at the Asylum Office. Tenders by Jan. 20.

Manchester.—The Tramways Committee invite tenders for the supply of electrical stores, etc., comprising cable; commutators, etc.; armatures, controllers, etc.; armature repairing material; fuses; ironmongery; rubber, etc.; trolley cord. Specifications from Mr. J. M. M'Elroy, Tramways Department, 55, Piccadilly, Manchester. Tenders by 10 a.m. on 15th inst.

London, S.W.—The London County Council invite tenders for the supply and delivery of about 6,850 tons of steel girder tramway rails, fishplates, and bolts and nuts, and for 4,100 tons of steel slot rails, and 1,490 tons of steel conductor tee rails required for electric traction on the Council's tramways. Specifications, etc., from Engineers' Department, and tenders to the Clerk, County Hall, Spring-gardens, by Dec. 15.

Sydney (New South Wales).—Tenders will be received at the office of the Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 30, for the supply and delivery at the departmental stores, Sydney, of telegraph, telephone, and electric light material. Specifications, etc., may be seen and tender forms obtained at the General Post Offices, Sydney, Melbourne, Brisbane, Adelaide, Hobart, and Perth.

Harrismith (South Africa).—The Town Council invite tenders for high-tension concentric feeder cable, low-tension triple-concentric distributor cable, low-tension service and street-lighting cables, joint-boxes, service boxes, and other accessories, and the supply of five 30-kw. transformers, four transformer pillars, high and low tension switchgear, etc. Specifications from Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster. Tenders by Jan. 18.

Portugal.—The *Diario do Governo* of Dec 2 contains an announcement that the project presented by the United Gas and Electricity Companies for the establishment of electric light in the new highway surrounding Lisbon will be on view for 15 days from Dec. 2, within which time reclamations have to be made. The *Diario* containing the above notice may be seen by those interested on application at the Commercial Intelligence Branch of the Board of Trade, 50, Parliament-street, S.W., any day between the hours of 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

RESULTS OF TENDERS.

Leeds.—The Markets Committee have accepted the tender of R. Middleton, Leeds, at £457. 11s., for an electric lift to hotel at New Market Hall.

Whitehaven.—The tender of H. Burns and Sons, Duke-street, Whitehaven, has been accepted for installing electric light and bells in six houses in Wellington-row.

Todmorden.—The Corporation have accepted the tender of Bruce Peebles and Co., Limited, for one 150-kw. steam set, one 75-kw. steam set, and one balancing booster set.

Leeds.—The Street-Lighting Department have accepted the tender of V. Roberts, Skinner-lane, Leeds, at £220, for installing a heating plant at the new offices and workshops at Springwell.

London.—The tender of Bruce Peebles and Co., Limited, has been accepted by the War Office for two 400-h.p. slow-speed continuous-current generators, 100 revolutions, direct-coupled to Robey engines.

King's Heath (near Birmingham).—The Urban District Council have accepted the tender of W. H. Gibbs, King's Heath, at £3,185, for erection of waiting-room and car-shed to accommodate eight cars, etc.

Whitehaven.—The Guardians have accepted the tender of Ramsay Bros., Phœnix Works, Whitehaven, at £432. 10s., for wiring and fitting up for electric light the workhouse and new infirmary at Whitehaven.

Barrow-in-Furness.—The Education Committee have accepted the tender of W. R. Thornton and Son, Ramsden-square, at £15. 12s., for the electrical lighting of the chemical laboratory in the higher-grade school.

Whitehaven.—The tender of H. Burns and Co., Lowther-street, Whitehaven, has been accepted for an installation of electric light in the new Sunday school, classrooms, etc., connected with Hogarth Mission.

Newport (Mon.).—Messrs. W. A. Baker and Co., Limited, have accepted the tender of Messrs. Johnson and Philips, Limited, at £381, for the supply of motors for changing the voltage of the electric current.

Brighton.—The Tramways Committee have accepted the tender of Dick, Kerr, and Co., Limited, for 10 cars at £5,100, and of the Brush Electrical Engineering Company, Limited, Falcon Works, Loughborough, for 10 cars at £5,085.

Blackpool.—The British Westinghouse Electric and Manufacturing Company, of Trafford Park, have placed an order with Messrs. Browett, Lindley, and Co., Limited, of Patricroft, for a 650-h.p. triple-expansion engine, for the Blackpool Corporation.

Oldham.—The Electricity Committee have accepted the tender of E. Stephenson, Shield-street, for the construction of pump-house, lodge, and tanks in connection with condensing plant, the construction of mains tunnel, footpath, and railings round site at the generating station, Greenhill.

Wednesbury.—The Town Council have accepted the tender of the National Electric Construction Company, Limited, of London and Wolverhampton, for supplying and fixing the electric wiring and fittings in the Wednesbury town hall, the municipal offices, the art gallery, public baths, and free library, for £464. 18s.

Dudley Port.—The Power Gas Corporation, Limited, have placed an order with the British Westinghouse Electric and Manufacturing Company, Limited, for the supply of two 250-h.p. three-cylinder single-acting producer-gas engines, solid-coupled to direct-current generators of equivalent power, to be installed at Dudley Port.

Swansea.—The Tramways and Electric Lighting Committee have recommended that the whole contract for tramway extensions be given to Messrs. Dick, Kerr, and Co., the amount being £81,751. All additions and deductions to be at schedule rates, subject to 2½ per cent. The firm to accept such cable as may be accepted by the Corporation at makers' prices.

Middlesbrough.—The Corporation have accepted the tender of the Brush Electrical Engineering Company, at £3,488. 10s., for the engine-house plant. Since the recommendation of the acceptance of the tender for boilers, the Horsfield Company intimated that there had been a mistake, and that they should have quoted £100 more, consequently Messrs. Hewett and Kellet's tender has been accepted.

Maidstone.—The Corporation have placed an order with the British Westinghouse Electric and Manufacturing Company for two 150-kw. shunt-compound generators for coupling to Messrs. Davey-Paxman's engines. These generators will deliver 300 amperes at 460 to 500 volts as shunt machines, and 275 amperes at 500 to 550 volts as compound machines. They will thus be available for either lighting or traction.

Swindon.—The Electricity and Tramways Committee have accepted the following tenders: J. G. White and Co., Limited, at £4,164. 8s. 7d., for steel poles, overhead line, etc.; the British Westinghouse Electric Manufacturing Company, Limited, at £750, for traction switchboard; the British Insulated and Helsby Cables Company, Limited, at £1,190. 9s., for tramway feeders, etc., including a two years' maintenance.

Kilmarnock.—The following tenders have been accepted by the Electrical Committee for plant required in connection with the proposed new generating station at Kilmarnock: boilers, Yates and Thom, Blackburn, £1,765; engines and dynamos, Dick, Kerr, and Co., Limited, London, £3,855; overhead crane, Carrick and Ritchie, Edinburgh, £268; storage battery, Tudor Accumulator Company, Limited, London, £1,201; switchboard and boosters, Cox-Walkers, Darlington, £1,989.

Burslem.—The Electric Lighting Committee have received the following tenders for the erection and completion of the generating station at Longport:

W. Grant and Sons, Burslem (accepted)	£2,100
W. Cook, Burslem	2,160
Bennett Bros., Burslem	2,168
T. Godwin, Hanley	2,235

BUSINESS NOTES.

TRACTION.

Woking.—The estimated cost of the Woking and Bagshot Light Railway is £82,504.

Blackburn.—The tramway extension into the Audley district has been formally opened for traffic.

Hackney.—The Borough Council are recommended to approve the proposed tramway along Amhurst-road.

Dalton.—The Urban District Council are urging the Barrow Corporation to extend the tramways into their district.

Bournemouth.—The Corporation tramways show a net profit for the six months ending September last of nearly £7,000.

Hastings.—Estimates of the quantities of materials required for the construction of the proposed tramways are now being prepared.

Rome.—The electric tramcars in Rome are now fitted with postal boxes, the contents of which are collected every quarter of an hour.

Mearns.—At a public meeting held in Mearns, it was agreed to ask the Glasgow Corporation to extend their tramway system to that district.

Folkestone.—The Town Council will apply to the Board of Trade for an order amending the 1901 order for the construction of tramways in the town.

Bath.—The British Westinghouse Company have received a further order for a number of complete magnetic brake equipments for the electric tramways.

Dartford.—The Board of Trade have confirmed the Dartford light railway extension order, authorising the construction of a light railway in the rural district of Dartford.

Walker.—The Town Council have decided to obtain a *locus standi* relative to the Bills of the Tyneside Tramways Company and the Newcastle Corporation to be introduced next year.

St. Marylebone.—The Borough Council are recommended by their Parliamentary Committee to adhere to their previous decision not to consent to the proposed Tottenham Court-road tramway.

Portsmouth.—There is a prospect of the present fares on the Corporation trams being considerably reduced owing to overtures which the Horndean Light Railway Company are making to this end.

Stalybridge.—The Stalybridge, Hyde, etc., Tramways Board propose to extend the tramways from Millbrook to Mossley. A sub-committee is considering the question of lighting the car-sheds.

Digitized by Google

Finchley.—It is believed that the power-house for supplying the trams with electric energy will be erected in the parish of Enfield. A sub-station will be established in Finchley on a site to be purchased.

Penarth.—The estimated maximum cost of the construction of a tramway between Cardiff and Penarth is put at £250,000. No decision has yet been come to either in favour or opposition to the scheme.

Leith.—At an extraordinary general meeting of the Edinburgh Street Tramways Company on Wednesday the shareholders confirmed the sale of the Leith tramways concern to the Town Council of Leith for £60,000.

Dunedin (N.Z.).—In connection with the electric tram service the City Council will instal another unit at the power-house at a cost of £1,400. This will ensure a continuous supply throughout the city and suburbs.

Preston.—The Hadfield's Steelfoundry Company, Limited, East Hecla Works, Tinsley, Sheffield, have received an order from Messrs. Dick, Kerr, and Co., Limited, for the points, crossings, etc, for the electric tramways.

Hove.—The Tramways Committee recommend the Council to refuse to entertain the proposal of the British Electric Traction Company to extend their tramways from the boundary of Hove and Aldrington to the railway station at Hove.

Rochdale.—The Corporation have authorised advertising on the electric cars. Some delay is likely to take place in fixing the value of the company's undertaking owing to the lamented death of Sir Frederick Bramwell, the arbitrator appointed.

Blackpool, St. Annes, and Lytham Tramways Co.—The directors of the Company report that the doubling of the line and its equipment for overhead traction has resulted in satisfactory receipts. It is proposed to carry the balance of £2,017 forward.

British Electric Traction Co.—The directors have declared the interim dividend to Sept. 30 last on the ordinary shares at the rate of 6 per cent. per annum, being at the same rate as in preceding years. The warrants will be payable on and after the 16th inst.

Perth.—The Town Council have definitely decided to appoint a consulting engineer to advise them in the reconstruction of the tramways system. The actual work of the reconstruction will be undertaken by the burgh surveyor and the electrical engineer.

Lowestoft.—The Corporation have ordered four more double-deck cars, equipped with motors and controllers of the Westinghouse 46 and 90 types respectively, from the British Westinghouse Company. The new cars will be similar to those already supplied by the company.

Bradford.—A committee has been empowered to negotiate for the purchase of 18,050 yards of land near to Foundry-lane and Bowling Back-lane, to be converted into a storeyard and sidings for trams. The Tramways Committee have approved plans and estimates amounting to £1,839 for the provision of special tramway facilities for the Cartwright Memorial Hall Exhibition.

Hull.—The Tramways Committee are experimenting with two collapsible car covers—one the invention of Mr. Kennington, the other known as the "Magrini," and built by Messrs. Milnes and Co. The Hedon-road route will be opened for traffic about the end of next week. There will then be six routes in operation in the city, exclusive of the section between Whitefriargate and Victoria Pier.

Liverpool.—The proposed tramway extensions, involving an expenditure to the Tramways Committee of £10,000, were under consideration at Wednesday's meeting of the Town Council, and a motion in favour of applying for a provisional order was negatived by 46 votes to 43. The necessary two-thirds of the members, however, were not present, and the proceedings are, therefore, abortive.

Derby.—There is a delay in the delivery of the rails for the tramways which the Corporation are getting from Belgium, and at the last meeting of the Tramways Committee it was asked whether any rails had been condemned. The official reply was to the effect that no rails had yet been delivered, and that the Corporation had a representative in Belgium who would not pass the rails unless they came up to the required standard.

Nelson.—A sub-committee has been appointed to consider the terms of lease of the Nelson section of the tramways to the Burnley Corporation. The Board of Trade have confirmed the order made by the Light Railway Commissioners transferring to the Corporation the powers conferred upon the Barrowford Urban District Council by the Barrowford Light Railway Order, 1901, and amending that order and the Nelson Light Railways Order, 1901.

Southport.—The Southport and Lytham Tramroad Company propose to deposit a Bill for a short extension of the time for constructing the proposed tramways, and also a clause empowering the Corporation, with other local authorities, to subscribe for shares or debentures in the company. The Corporation will support the application. Experiments are being made with a car which is so designed that a conductor is not required. It is popularly called the "one man car."

Yorks.—The Yorkshire Electric Tramways Construction Syndicate, Limited—a Wakefield company—intend to apply to the Light Railway Commissioners for powers to construct a light railway or tramway from Church-street, Dewsbury, along Vicarage-road and Long Causeway into Dewsbury Market-place, and then up Wakefield-road, through Bank Top, Chickenley Heath, Ossett-street Side, and Dale-street, Ossett, into Station-road, Ossett, with a junction into and along Bank-street, Ossett.

Cardiff.—Mr. Arthur Ellis, the electrical engineer, submitted to a special meeting of the Tramways Committee on Tuesday a revised list of fares which has been concerted with the object of equalising the distance[illegible]mmittee, after some discussion, adopte[illegible] into operation on Jan. 1, and will re[illegible] The electrical engineer depre-

cated the introduction of the transfer system, pointing out that it was very often abused.

Pontypridd.—At the last meeting of the District Council a letter was read from the British Electric Traction Company, stating their inability to accept the terms offered by the Council in regard to the horse tramway from Pontypridd to Hafod. It was resolved to apply to the Board of Trade to appoint a referee, and to ask for a more detailed report from the company of the property proposed to be purchased. The amount offered was £2,370.

Army Tractors.—Messrs. R Hornsby and Sons, Limited, of the Spittlegate Ironworks, Grantham, have received official information from the War Office that their engine has won the first prize of £1,000 and bonuses amounting to £180 in the open competition for military tractors. It is an oil tractor, propelled by an oil-engine of the Hornsby-Akroyd type, constructed on the lines of an ordinary traction engine, spring mounted at both ends, and fitted with the usual speed-change gears. Its weight with fuel and water does not exceed 13 tons.

West London.—The London United Tramways have given a further order to the British Westinghouse Company for sub-station plant, including two 250-kw. rotary converters, seven 100-kw. oil-insulated self-cooling transformers, a switchboard for the control of the above apparatus, and the necessary details. A large number of rotary converters are now going through the Westinghouse shops, including 500-kw., 800-kw., 1,200-kw., and 1,500-kw. units, for, *inter alia*, the District Railway, Metropolitan Railway, and North-Eastern Railway.

Walsall.—An official inspection of the new tramways constructed by the Corporation has been made by Lieut.-Colonel Yorke on behalf of the Board of Trade. The lines are to Walsall Wood, Willenhall, and along the Birmingham-road to the borough boundary. The working of the lines will commence at the beginning of the new year, when the Corporation also take over the tramways within the borough at at present let on lease to the South Staffordshire Tramways Company. Altogether rather over 12 miles of tramways in the district will be under municipal control.

Sheffield.—The Tramways Committee, with the assent of the Corporation, have recently made a grant of £5,000 out of their profits to the Sheffield University endowment fund. The construction of the single line in Shoreham-street is to be proceeded with at once, also along Suffolk road, Queen's-road, and Bridge-street. Alderman Clegg, at Wednesday's meeting of the Town Council, paid a tribute to the services rendered the Tramways Committee by Mr. Fell, who is about to vacate the position of tramways manager to take up a similar post with the London County Council.

Swansea.—The Tramways Committee propose to appoint two inspectors to superintend the laying of the rails and to continue the engagement of an assistant surveyor in connection with the new tramways. Major Druitt, who has been enquiring into the objections of the Oxford-street tradesmen to a tramway being laid through that street, has issued his report stating that the Board of Trade cannot interfere, having regard to the powers held by the Corporation, and leaving it to the latter to decide whether they, in the face of strong opposition, will construct the tramway in question.

Richmond.—After having debated the question at various meetings within the last few months, the Tramways Committee have decided to recommend the Town Council to give their consent to the company to construct lines over Kew Bridge connecting the authorised and constructed lines on either side of it. This the Council decided to do on Wednesday on conditions which include a bond of £10,000 to complete the line within 12 months. By a supplementary scheme, for which the company will seek parliamentary powers next session, it is proposed to link up Hammersmith with Barnes, Mortlake, and Richmond.

Eastbourne.—At the last meeting of the Town Council a councillor advocated the introduction of electric trams, and assured the Council that if they did not take the necessary steps the people in the east end would invite a company to introduce an electric tramway system. The motor 'buses had not begun to come up with the 'buses they had driven off the road. The 'buses rushed by without taking the slightest notice of would-be passengers, and it was very difficult, unless one had the agility of a hound, to overtake them. The Mayor ruled discussion out of order, but promised that the resolution of the recent mass meeting in favour of trams should be considered by the committee.

Wolverhampton.—A special meeting of the Town Council has been held to consider the details of a Bill proposed to be promoted in the next session of Parliament to empower the Corporation to construct tramways, and make further provision with regard to their electricity undertaking. It is proposed to make tramway extensions in the direction of Wednesfield, at a cost of £11,000, to reconstruct a bridge over the canal at a cost of £2,000, purchase land for shelters, etc., at a cost of £300, and widen Queen-square and Victoria-street and erect buildings at a cost of £30,000. The Council approved the preamble of the Bill, and also several clauses relative to the tramways.

Salford.—Complaints were made against the management of the tramways at the last meeting of the Town Council, and the Chairman of the Committee, replying, stated that they at the present time were studying economy in every possible direction, by reason of the fact that during the recent bad weather the receipts of the tramway undertaking had shown a decrease of £400 a week. He contended that the complaints that had been levelled against the management of the Salford tramways applied with equal force to the management of Manchester and other towns. He added that the committee had found from experience that the short routes did not pay so well as the long routes.

Bury.—The line in Bolton-road is to be doubled, and the Fairfield section from opposite the Brown Cow to the workhouse boundary extended. It is decided to proceed with the work of construction on those routes not interfered with by the present tramway company. Specifications have been prepared and tenders obtained for the supply

Digitized by Google

and delivery of rails, fishplates, fishbolts, anchor plates, tiebars, points and crossings, and bonds. Various interviews have taken place with the authorities of Whitefield and Radcliffe in reference to the construction and working of the tramways within their districts in conjunction with the Bury Corporation tramways, but nothing has yet been decided.

North-Eastern Railway.—The North-Eastern Railway Company on Sunday carried out further trials on the newly-electrified line between Newcastle and Monk Seaton Station. The distance is about 10 miles, double track. The trials continued from morning until after darkness fell and were thoroughly satisfactory. The experimental train was made up of two motorcars and two trailers. Several runs were taken at both express and ordinary speeds, and a general test made of the braking and electric heating arrangements. A speed of nearly 45 miles an hour was attained, the rate being reached in 35 seconds from rest. A number of officials were present at the trial, including Mr. Chas. Merz, consulting engineer to the company.

Proposed "Tube" Extensions.—The Islington Borough Council have decided, after correspondence with Sir George Bartley, their representative on the Royal Commission on London Locomotion, to forward recommendations with respect to two new "tube" extensions in North London in connection with those nearing completion. The first scheme is for an extension from Highbury-corner to the tramway terminus at the Archway, and thence across the borough from east to west, giving greater facilities between the West-end, Islington, and Stoke Newington. The second scheme is to extend the "tube" of the Great Northern Railway, which terminates at Finsbury Park, to the Alexandra Palace, and so give greater facility for reaching London's municipal palace.

St. Pancras.—The town clerk has received a communication from the clerk to the London County Council expressing the thanks of the Highways Committee of the Council for the consent given to the construction of an electric tramway along Tottenham Court-road, and adding that the Improvements Committee have decided to recommend the County Council to proceed forthwith with the authorised widening of the southern end of Hampstead-road, the Highways Committee having concurred in this course. The Highways Committee confidently rely upon the Borough Council's aid in connection with the promotion of the Bill to authorise the Tottenham Court-road tramway. The Council on Wednesday confirmed their decision to sanction the proposed tramway.

Additional Traffic Returns.—Anglo-Argentine, £1,979 increase; Barcelona Ensanche y Gracia, £123 increase; Barcelona, £80 decrease; Brisbane, £18 decrease (month of November, £10,544, increase £253), British Columbia Electric (month of March), gross earnings £10,352, net income £2,659; Buenos Ayres and Belgrano Electric, £303 decrease (month of November, £14,142, increase £444); Calcutta, £272 increase; Cape Town (month of October), receipts £16,229, expenditure £9,044; Isle of Thanet Electric, £40 increase; Lisbon Electric (month of October), receipts 93,725 milreis, expenses 50,350 milreis; Mexico Electric (month of November), receipts £47,350, expenses £27,600; Perth Electric, £179 increase; Port Elizabeth (month of October), receipts £3,972, expenditure £2,879.

Dewsbury.—The Town Council have now decided to give the requisite notice to purchase the undertaking of the British Electric Traction Company within the borough. It is stated that the basis of purchase will be the full cost of the lines and equipment, including the parliamentary expenses of the traction company, plus 20 per cent. On the day that the purchase takes place the Corporation will grant a lease to the company for 28 years at a rent which will be equal to the price paid for the concern. The Corporation will not permit the traction company to assign their lines to a subsidiary company without their consent. At the end of the 28 years the traction company will have the option of entering into a further lease of seven years on the same terms. It is stated that the total price to be paid for the tramways on the above basis will be about £70,000.

Belgian Rails.—The *Daily Telegraph* had a long letter from its special correspondent at Liège on Monday discussing the question of Belgian tramrails, and giving as the reason why Belgian rails are produced more cheaply than the British-made article that the Belgian manufacturers use basic steel while the British firms mostly employ Bessemer steel in the manufacture of the rails. With this suggested solution of the problem we beg to most emphatically disagree. As a matter of fact, the British firms almost exclusively use basic steel, which has long been an important portion of the output of English steelworks. One of the chief reasons which we believe is responsible for the difference in price between the Belgian and British made rail is that in Belgium there is complete freedom from trade union rules, which allows of a lower rate of wages and longer working hours.

South London Tube.—The Southwark Borough Council are taking action against the original Baker-street and Waterloo (Extension) Railway Company on account of an alleged refusal on the part of Mr. Yerkes to carry out the agreements of the Act of Parliament under which the scheme was sanctioned. The Act provided for the provision of an underground station and subway crossings at the Elephant and Castle. The original company has, however, been bought up by Mr. Yerkes, who informed a deputation from the Council that owing to the number of electric cables, pipes, mains, etc., at the Elephant and Castle, it would be too expensive to carry out the undertakings of the old company in their entirety. He undertook to consider the question of providing crossings, but the station would be placed in the London-road. The Council do not consider this arrangement satisfactory.

Brighton.—The detailed accounts of the Corporation tramways undertaking for the year ended March 31 last are now available. The traffic receipts for the year amounted to £43,468. 17s. 4d., the number of passengers carried being 10,432,528, and an item of £231. 6s. under the heading of rents brought the income on the revenue account up to £43,700. 3s. 4d. The principal items on the paying-out side of the account were £13,036. 14s. 2d. for salaries and wages, £9,300. 16s. 3d. for electrical energy, £1,238. 5s. for miscellaneous traffic expenses, and £4,680. 8s. 11d. for repairs and renewals. The total expenditure on the revenue account was £31,615. 8s. 1d., leaving a balance of £12,084. 15s. 3d. to be transferred to the net revenue account to meet interest, sinking fund charges, etc. These absorbed £7,949. 16s. 2d., the deficiency on the previous year, amounting to £3,051. 5s. 11d., was repaid, leaving a credit balance of £1,083. 13s. 2d. The net expenditure on the capital account at the beginning of the year had been £177,870. 10s. 11d., and during the year this was increased to £205,041. 16s. 5d., the chief items being £15,707. 15s. 8d. for permanent way and overhead equipment, £6,285. 13s. 10d. for land and buildings, £9,827. 19s. 6d. for rolling-stock, and £1,250. 16s. 11d. on machinery and plant. Another attempt is to be made at the next Town Council meeting to take the necessary vote to approve the promotion of a provisional order for the tramway extension in Preston-road.

A Novel Form of Electric Railway Car.—A correspondent to the *Times* describes for the benefit of railway managers in this country an interesting endeavour which has recently been made by the Illinois Central Railway in Chicago to combine the good features of the corridor and side-door car in a new design of vehicle, which has side doors, but is not divided into compartments. There are gangways down each side of the car after the fashion of our corridor trains, and all the doors (which slide instead of opening outwards) can be manipulated by pneumatic power by a "trainman," who stands inside the car. This prevents the waste of time arising from porters and guards having to run alongside the train to shut the doors, as is done in this country; while the gangways enable passengers to find their seats after they have boarded the car, instead of occupying valuable time in searching for a compartment to their taste. The new type of car is stated to have given great satisfaction to the authorities of the Illinois Central Railway, who have found it preferable both to the ordinary American type (which is best exemplified in this country on the Central London Railway) and to the British type of side-door compartmental car which was given a trial in Chicago at the time of the World's Fair in 1893. It would be interesting to know whether the attention of our London railway authorities has been directed to this latest invention in suburban railway carriage construction, and, if so, whether they intend to take any steps to give it a trial. The Chicago cars have steel frames, which make them considerably lighter than wooden cars of the same size.

London Suburban Tramways.—Speaking at the ordinary meeting of the Lea Bridge, Leyton, and Walthamstow Tramways Company on Tuesday, the Chairman stated that the Leyton District Council gave the company the statutory notice of their desire to purchase the portion of the tramway which was situated in the Lea Bridge-road. The Walthamstow Council had the power to give the company notice to sell the portion of line which was within their district, but they failed to get the statutory number of members at their Council meeting, and they could not, therefore, give this notice. That portion of the line in the Lea Bridge-road would consequently remain with the company for six years from now. The remaining portion of the line in the Lea Bridge-road was in the county of London, but the London County Council had no power of purchase for some years yet, and that was the position of the remainder of the company's lines which were within the district of the Leyton Council—that was to say, they could not compel the company to sell those portions of the line. Having regard to the unsettled position and the possibility of an arbitration, it was not desirable to discuss the matter in an open meeting, but he might say that informal communications had passed between the Leyton Council and the company with reference to a sale of the entire undertaking to the former, and the Leyton Council had given notice of an application to Parliament for next session with reference to the tramways. At the ordinary general meeting of the Great Eastern London Suburban Tramways and Omnibus Company on Tuesday, the Chairman referred with satisfaction to the results of the year's working in view of the "inordinate time taken by the West Ham Corporation in constructing their tramways."

London County Council.—At the last meeting of the London County Council on Tuesday the Highways Committee were able to make the satisfactory announcement that it may be possible to commence the electrical working of the New Cross and Greenwich, etc., sections of tramways by the end of the present year. The reconstruction of the tramways is completed, and the electric cables are laid while the arrangements at the sub-stations and for the provision of the supply of power from the London Electric Supply Corporation's station at Deptford have reached an advanced stage. The committee think that the inauguration of electrical traction on these lines will naturally be an event of considerable interest to the districts concerned, and they have accordingly given instructions for an invitation to be extended to the members of the different metropolitan borough councils through whose districts the line pass to be present at the inspection by the Board of Trade. At an earlier stage of the meeting Mr. E. Collins called attention, on the reception of the report of the Finance Committee, to the fact that, judging by the present receipts of the Council's tramways, the receipts for the year would be short of the amount estimated by some £55,000, and he suggested that the business auditor be employed to audit the tramway accounts on business lines. Lord Welby, chairman of the Finance Committee, thought there was no doubt that, owing to the changes in the system, the receipts would not be as much as estimated, but it was too early to forecast what the deficiency might be. During the sitting a petition was presented from 200 medical men asking that the drivers and conductors of the Council's tramcars should be provided with seats on their cars. The Council received tenders for (*a*) the supply, etc., of three-phase generators at the Greenwich tramways electricity station; and (*b*) for electric light, wiring, etc., at tramways, car-sheds, and sub-stations. These were referred to the Highways Committee.

LIGHTING AND GENERAL.

Bootle.—A number of extensions of distributing mains have been approved.

Stockton.—Efforts are being made to increase the day load by supplying motors.

Leyton.—The Urban District Council are about to borrow £5,000 for electrical extensions.

Spalding.—The proposal to apply for a provisional order for electric lighting has been postponed.

Dalkeith.—Messrs. Crompton and Co. have been authorised to erect the five additional arc lamps.

Folkestone.—The agreement with the electric light company for street-lighting will expire on July 30 next.

Paignton.—A special meeting of the ratepayers' association is to be held to discuss the electric lighting question.

Holyhead.—The Urban District Council have signed a contract with the National Electric Construction Company.

Dewsbury.—The electrical engineer is about to lay down 44 yards of electric main to the new circus in Foundry-street.

Elland.—The Urban District Council propose to apply for sanction to borrow £4,000 to carry out electricity extensions.

Watford.—The Urban District Council have decided to seek an offer for the purchase of the electric lighting undertaking.

Denny (Stirling).—The Town Council have postponed till June consideration of the advisability of applying for an electric power order.

Wednesbury.—The Council have authorised the expenditure of £464 in lighting the town hall and other public buildings by electricity.

Bolton.—The Electricity Committee have invited the Horwich District Council to confer with them on the question of supplying electric current in Horwich.

Sheffield.—An enquiry has been held into the City Council's application for power to borrow £10,000 for the purchase of electric motors to be let out on hire.

Andover.—The Council are in favour of the application of the Southern District Electricity Company, but will formally object so as to maintain their *locus standi*.

Loughborough.—The Town Council on Monday ratified their decision in committee to adopt the scheme for an electrical undertaking prepared by Mr. C. H. Gadsby.

Wrexham.—The borough electrical engineer in his last report states that the destructor worked satisfactorily during November, and had destroyed all the refuse delivered.

Keynsham.—The District Council have decided to apply next year for an order to supply the district with electric light, the current to be taken from the Somerset Electric Power Company.

Horwich.—The Lancashire Electric Power Company having informed the Council that they would be in a position to supply electricity in bulk by Jan. 1, 1905, an interview is to be arranged.

Kingskettle.—The National Telephone Company have introduced a line into Kingskettle, and most of the subscribers have now been connected with the exchange, which is at the post office.

Sleaford.—The Electric Lighting Committee's last report shows an additional 111 lamps connected during the quarter; 3,920 units were consumed last month, as compared with 2,408 last year.

Bury.—The extension of works for providing accommodation for the traction plant has been proceeded with. An application for current for motor power at 1d. per unit is being considered.

Middlesbrough.—The report of the Electric Lighting Committee, containing particulars as to the proposed extension of the existing plant, involving an outlay of some £15,000, has been confirmed.

Farnham.—At the last Urban District Council meeting the deputy clerk added that the Board of Trade had merely acknowledged receipt of the Council's application for extension of their order for 12 months.

Southport.—From Jan. 1, 1904, the charge for electricity for motors is to be 2d. per unit; where the consumption of current exceeds 36 hours per week per brake horse-power installed, the charge to be 1½d. per unit.

Kensington.—Notices from the Brompton and Kensington Electric Supply Company relative to proposed extension of their mains, etc., in Bute-street, Gloucester-road, and Harrington-gardens have been agreed to.

Ilfracombe.—Arrangements have been completed whereby a continuous night and day trunk service between the exchanges comprising the Barnstaple and Ilfracombe areas and any trunk centre in Great Britain has been opened.

Hereford.—We learn that the Corporation's electricity department have now over 11,000 lamps connected, and are just about to lay 250 yards of single cable laid solid at a cost of £225. Several other main extensions are being considered.

Stock Exchange.—The Stock Exchange Committee have appointed Dec. 16 special settling day for Havana Electricity Company's 15,000 shares of £10 each, £8 paid, Nos. 1 to 15,000, and have ordered the said securities to be quoted in the official list.

Long-Distance Telephone.—The Postmaster-General has notified the Liverpool Chamber of Commerce that arrangements have been made for telephonic communication between Lancashire and various French towns. The scheme only awaits French legislative sanction.

Blantyre.—It is proposed to form a strong electric power company which will erect premises on the site of the old Turkey-red dyeworks at Blantyre. The scheme contemplates drawing the company's water supply from the Clyde within the boundaries of the Blantyre estate.

Thirsk.—The work of laying the cables and fixing the posts has made good progress, and it is expected that the streets will be lighted by electricity on Jan. 1 next. The company have already lit the public streets of the neighbouring village of Sowerby with electricity.

Cardiff Docks.—The Cardiff Railway Company have distributed circulars amongst their tenants at the docks asking for certain information as to the extent to which they may be able to supply electric power and current under a scheme which they have had under contemplation for some time past.

Merton.—The Electric Lighting Committee of the parish are considering a letter from the Wimbledon District Council stating that they had received application from the owners of the Polytechnic and Raynes Park estates to light roads thereon with electric light, and asking if this authority had any objection.

Greenock.—Plans were lodged with the master of works on Tuesday for the Messrs. Wright's new theatre to be erected at the corner of Argyle and West Stewart streets, Greenock, and the architects for which are Messrs H. and D. Barclay, Glasgow. A complete installation of electric light will be provided.

Stroud.—The Council have consented to the application of the Gloucestershire Electric Power Syndicate, Limited, in respect of the application for a provisional order for lighting the area included in that rural district, on the understanding that they should grant similar rights to other companies which might apply.

St. Annes.—Application is to be made for sanction to borrow £4,000 for extension of mains and services. The engineer on Wednesday reported 22 applications for 1,010 lights, and for two convalescent homes. Units sold to Oct. 31 were 254,208, against 64,823 last year, and the number of consumers is 214, against 140.

Newport (Mon.).—The Council have adopted a report with reference to the decision to erect a sub-station on Cardiff-road, on which the borough electrical engineer reported that if the machinery for such sub-station were erected at the Llanarth-street works the building of the sub-station might be deferred for about 12 months.

Bramwell and Harris.—We are informed that, notwithstanding the recent loss which the firm sustained by the death of Sir Frederick Bramwell, the business of "Bramwell and Harris" will be carried on as heretofore at 5, Great George-street, Westminster, and also at Edinburgh and Cardiff. The name of the firm will remain unchanged.

Hastings.—The Electricity Committee are about to equip the three electric light sub-stations with the Andrews duplicate mains apparatus, and have accepted the offer of Cowans, Limited, Salford, for one complete set for a total current of 75 amperes for £126, with a 12 months' guarantee. The estimated cost of fixing and connecting up the same is £24.

Perth.—The Electric Lighting Committee seem to experience some difficulty in finding room—if any be required—for the alleged smoke nuisance at the electricity works, and they have requested the Sanitary Committee to meet them in conference and discuss the matter before any suggestion is adopted that would lead to the spending of money.

Salford.—The Town Council have resolved to take over the Prestwich electric lighting provisional order and to apply for sanction to borrow £5,000 to cover the cost of laying the necessary cables, etc. By agreement with Prestwich the Council will charge ½d. per unit more than the price in Salford. A consumption of about 40,000 units is expected.

Reading.—At the last Town Council meeting the following resolution was proposed and lost: "That this Council do now resolve to seek parliamentary powers for the purpose of lighting from their own works such streets and thoroughfares, as the Council may deem expedient, of the town as are or may from time to time come under its jurisdiction."

New Malden.—The Electric Lighting Committee have fixed the compulsory area, and have approved the form of the draft provisional order. The amount required to carry out the work is estimated at £20,000. At the last meeting the clerk reported that the Twickenham, Teddington, and District Electric Supply Association had given notice to apply for an order also.

Glasgow.—At the last Council meeting the minutes of the Electricity Committee were considered. They recommended the extension of the generating stations at Port Dundas and Pollokshaws-road. Objection was taken to the proposal, and the necessity for unification of the whole of the electrical departments was urged, and during the discussion the house was counted out.

Swansea.—The engineer's last report states that since his previous report the number of equivalent 8-c.p. lights applied for had been 1,074. The committee have decided to extend the electric lighting main, provided the Church Army Home authorities, who desired to instal the system in that institution, undertook to take a minimum supply for a period of not less than three years.

Newquay.—With reference to the notice of the Southern District Electricity Corporation *re* an intended application for an electric provisional order for Newquay, the Urban District Council have agreed to endeavour to obtain advice on the terms of the proposed order from Mr. Harold Dickinson, of the Leeds Corporation electricity works, and also from the Leytonstone Urban Council's electrician.

Merthyr.—The Lighting Committee have resolved in respect to the electric lighting of High-street, Merthyr, that the surveyor prepare a plan showing the sites of the proposed arc lamps, together with a comparative estimate of the cost showing the combined system of lighting by electricity and gas, and by the providing of extra gas lamps without arc lamps. It has also been resolved to erect four lamps upon another road.

Powis Castle.—The castle is now undergoing alterations. The contract was over £30,000, and the building alterations and renova-

Digitized by Google

tions are now being proceeded with. Up to last week the castle was illuminated either with oil lamps or wax candles. Now, however, an electrical generating station has been built under the castle rock, and a few nights ago 600 electric lights were switched on for the first time in the ancient stronghold.

Elgin.—At a meeting of the South U.F. Church Literary Society last week, Bailie Davie made a most eloquent speech in favour of the introduction of the electric light. Other speakers followed, and a hearty vote of thanks was awarded the bailie, the chairman remarking that he thought the society had done a public service in taking up this matter, and hoped the Town Council would soon take up consideration of the lighting of the town.

Ealing.—The output of current for the half-year ending September shows a considerable increase over the corresponding half last year, and the total costs for the half-year are ·23d. per unit lower, despite the increase in rates from £193 to £617 for the half-year. A large proportion of this sum has been returned to the borough in the district fund. The financial result for the two summer quarters compares favourably with that for the corresponding period last year.

Yarmouth.—The electrical engineer on Wednesday reported as follows: there have been nine new consumers, representing 743 8-c.p. lamps, connected up during the month, making a total of 442 consumers, representing 21,718 8-c.p. lamps, now connected to the mains. The committee recommended that the arc lamps on the Esplanade be removed from the columns from Jan. 1 to the week previous to Easter, and that the incandescent lamps be lighted till 12 o'clock only.

Acton.—The District Council have decided to oppose the Metropolitan Electric Supply Company's application for a provisional order to supply electricity in the district, and they have appointed a sub-committee, consisting of Messrs. King, Jarratt, Poulton, Morris, Athawes, Monson, Ainsley Baldwin, and Hunt to consider Mr. Trentham's report. The chairman and Mr. Trentham are to seek an interview with the managing director of the Metropolitan Electric Supply Company.

Tottington.—The Parliamentary Committee of the District Council have under consideration a letter from the Lancashire Electric Power Company explaining the position of the company, which is about to commence the erection of a generating station at Outwood, near Radcliffe. The company saw no reason why an agreement should not be effected between the Council and themselves for the supply of electricity in bulk from a fixed date. Current could be supplied by Dec. 1 next year.

Electric Light for Vehicles.—Messrs. Wilson and Stockall, of the County Carriage Works, well known as makers of ambulance bronghams, have introduced electric light for illuminating the interior of their vehicles. The current is obtained from a dry battery, with a life of 60 hours, which can be placed in any part of the vehicle, and the lamp is so arranged that it can be fitted to either the roof, back, or sides of the interior of the vehicle. By means of a switch three grades of light can be obtained.

Destructors.—We are informed that the Horsfall Destructor Company, Limited, Leeds, have recently shipped two important destructor plants to South Africa for the cities of Bloemfontein and Durban. Among other new destructors upon which the company is at present engaged we note plants for Folkestone, Bromley, Chiswick, Swansea, Batley, Stourbridge, and Gosport. Several of these destructors will furnish power for electric lighting, sewage pumping, etc., in addition to the sanitary disposal of refuse.

Fulham.—The following meters are to purchased: 150 Ferranti 10-ampere meters for £365. 12s. 6d., 150 Westinghouse five-ampere for £566. 5s., making a total of £931. 17s. 6d. The borough electrical engineer has submitted the undermentioned statistics: connections—previously reported, 958, or 42,052 8-c.p.; from Nov. 13 to Nov. 26. 1903, 28, or 1,178 8-c.p.; making a total of 986, equivalent to 43,230 8-c.p. There are also 16 consumers not ready for connection and four who have not yet paid deposits.

Huddersfield.—At a special meeting of the Town Council on Tuesday the application to the Board of Trade for a provisional order in the next session of Parliament for power to supply the urban district of Golcar with electricity for public and private purposes was sanctioned. The Mayor (Alderman Inman) said that a similar scheme for Linthwaite cost £7,000. The whole of the contemplated scheme for Golcar would cost £25,000, but it would not be done all at once, and only in such portions as showed prospect of a profit.

Tonbridge.—The resident engineer in his last report states that three applications for light have been received since the last meeting. The number of consumers now totals 92, equivalent to 3,179 lamps of 8 c.p. The engineer has made photometric tests of the illumination of the footways with incandescent gas and electric lamps respectively, and has submitted in tabular form the result of his experiments. These appear to be in favour of electric lamps, but before making any recommendation on the subject further tests are to be made.

Topsham.—A meeting was held last week to receive the report from the committee appointed to enquire into the feasibility of providing an electric light installation for the town. The committee are convinced that the introduction of electric light is quite feasible, and that it would be a decided acquisition to the town. After a lengthy discussion, the meeting decided that the scheme should be proceeded with, and a provisional board of directors was appointed, with Captain T. Holman as chairman and Mr. H. C. Gould as secretary.

Willesden.—At Tuesday's meeting of the District Council the draft agreement for sale of the electricity works in Taylor's-lane to the North Metropolitan Electric Power Supply Company was approved, subject to such alterations as the solicitor and electrical engineer have already made or may consider necessary for protecting the interests of the Council, and subject to the insertion of a clause enabling the Council to require payment at any time in cash of any balance which may be due from the company on giving six months' notice to that effect.

Clacton.—The sub-committee appointed to wait on the Board o Trade with a view to obtaining a further postponement of the revocation of the electric lighting order has had an interview with Mr. Pelham, secretary to the Board of Trade, who said that he thought he might go so far as to say that the Board would not consider as to revoking the order for another 12 months, and they would not then revoke it without giving the Council ample notice.

St. Marylebone.—A long article in the *Times* of yesterday lays the views of a correspondent on the St. Marylebone deadlock before the public. The writer claims that if the Council get their Bill next year, the loan of two millions required will involve the ratepayers in an annual loss of £50,000. This figure is arrived at on the supposition that the profits from the electric lighting cannot be increased beyond the present figure of £51,000 per year. In conclusion, a compromise is recommended by which the St. Marylebone Council would pay the company to let them off the terms of the arbitration.

Electric and General Investment Co.—The directors have declared the following interim dividends: at the rate of 6 per cent. per annum on the Company's preference shares for the six months ending 31st inst., being 3s. per share, to the shareholders registered in the books of the Company on that date; at the rate of 10 per cent. per annum on the capital paid up on the ordinary shares of the Company, being 1s. per share, for the six months ended 30th ult., to the shareholders registered in the books of the Company on Nov. 30. Both dividends will be paid, less income tax, on Jan. 1, 1904.

Ventilation with Electric Heating.—The King's Room at the Criterion has been fitted up with a permanent installation of electric heaters and fans and screens and slotted panelling around the walls, which form the elements of the Glover-Lyon system of ventilating. A temporary installation of this system was demonstrated by Dr. Lyon last summer at the Camera Club, and then described by us. The installation was carried out by Dr. Lyon, under the supervision of the engineering firm of Shone and Ault, and when tested at a large dinner on Monday gave universal satisfaction. An elegant switchboard hidden in the lower panelling controls 10 rows of heaters, three ozone tubes, one supply blower, and one extractor fan. The air, purified and heated, passes through the slots, which commence at about 12ft. from the floor, and is extracted on the opposite side. The results were favourably commented on by those present.

Swansea Telephones.—At the Telephones Committee on Monday the manager reported that 456 subscribers' lines had been connected. Two hundred and fifty-two orders were still in hand, and 94 had been obtained since the opening of the exchange, while the prospects of obtaining new orders was encouraging. The subject of intercommunication arose. The chairman did not favour it, because, once demanded, they could not withdraw it. The municipal system was increasing by nearly 100 subscribers per month, and if an exchange of 2,000 could be obtained, and the National system diminished to 500, the Corporation would, if there was free intercommunication, have to give the National subscribers free intercommunication. The 500 subscribers necessary to place the Corporation in a legal position to demand intercommunication would probably be obtained within a fortnight. A sub-committee was appointed to go into the matter.

Eastbourne.—The Electricity Committee propose to supply energy at a charge of 3d. per unit for exhibition purposes only, subject to a minimum charge of £4 a year. With regard to the electrical exhibition, the *Eastbourne Gazette* says: "When it was announced on Saturday morning that owing to the 'great success' of the exhibition there would be free admission in the evening some sceptical people jumped to the conclusion that the true reason was the paucity of the attendance. The charge for entrance has been the very modest amount of 3d. On enquiry at the town hall on Saturday afternoon, about half-past four, I learned that some 2,000 people had already visited the exhibition; and, what was still more satisfactory, I ascertained from one of the principal local stallholders that he was gratified with the amount of business done and the number of enquiries received. The local tradesmen who were represented may be justly congratulated on the spirit, enterprise, and taste of which their interesting displays of lamps, radiators, and fittings gave evidence."

London County Council.—On Tuesday it was agreed to lend the Hampstead Borough Council £14,145; the St. Pancras Borough Council £10,000; and the Stepney Borough Council £1,902 for the electric light installations. The following notices to lay mains, etc. under Electric Lighting Acts and Orders were agreed to: from the Blackheath and Greenwich District Electric Light Company, along Humber-road and across Westcombe-hill; from the Brompton and Kensington Electricity Supply Company, along Bute-street and along portions of Gloucester-road and Harrington-gardens; from the Charing Cross and Strand Electricity Supply Corporation, under the St. Martin's Order, 1899, intention to build boxes at the corners of James-street and Haymarket, at the corner of St. Martin's-street and Whitcombe-street, and in Whitcombe-street opposite to the gallery of the Society of British Artists, the same company, under the Strand District Order, 1896, to lay mains along a portion of Tavistock-street, the Holborn and St. Giles's Order, 1898 (No. 2), to lay mains along a portion of Drury-lane; from the County of London and Brush Electric Lighting Company, a transformer box, Vernon-road; from the Metropolitan Electric Supply Company, under the Mid-London Order, 1889, along Lincoln's-inn-fields, Gate-street, New Turnstile, High Holborn, Southampton-street, Bloomsbury-square, Bedford-place, and Russell-square. Notices to lay mains under orders granted to local authorities were also received as follows: from the Hampstead Borough Council, along portions of Lincroft-gardens, Stanley-gardens, Eton-avenue, Upper Park-road, along Glenlock-road and Antrim-street, and across Haverstock-hill; from the Islington Borough Council, along portions of Blackstock-road and Mount-grove-road; and from the Stepney Borough Council, along Horseferry Branch-road and across Medland-street.

Digitized by Google

Dunfermline.—The National Electric Construction Company do not now intend to proceed with their application for a provisional order for supplying the district with electricity, owing to the opposition threatened by the Town Council, who propose to apply for parliamentary powers.

Birkenhead.—After Jan. 1, 1904, the charges for electrical energy for power and heating purposes within the borough are to be at the following rates: for the first 500 units per quarter, 2½d. per unit; beyond 500 and up to 1,500 units, 2d.; from 1,500 to 5,000 units, 1½d.; from 5,000 to 10,000 units, 1⅜d.; in excess of 10,000 units per quarter, 1¼d. per unit.

Trowbridge.—At a recent special meeting of the Chamber of Commerce the future of Trowbridge with regard to electric lighting was discussed. It will be remembered that the Urban District Council, after advertising, received applications from companies who were willing to negotiate, and at the present time a draft agreement with a company is under consideration. After discussion, a resolution was passed favouring the leasing of powers under the provisional order, with the option of purchase by the Council at the expiration of a given time.

The Telephone at Railway Stations.—At the last meeting of the Newcastle Chamber of Commerce letters were read from the various railway companies, the National Telephone Company, and the General Post Office respecting representations made by the Chamber as to the desirability of fitting telephone boxes on railway station platforms. The North-Eastern Railway Company agreed to fit telephone call boxes at its most important stations, the National Telephone Company will instal the wires and instruments, and the system is to be ready for use early in the New Year.

Cupar.—Mr. Houston, Hillside Foundry, has just introduced electric lighting into his works at Cupar. A dynamo of 105 volts has been installed, which supplies two large Stewart arc lights and some 60 Ediswan lamps of 16 c.p. each throughout the works. The dynamo has been driven during the last few days by the ordinary 9-h.p. steam-engine which is used for the different machines in the works, but a smaller engine of higher speed is in course of erection, and will be used for the dynamo alone. Messrs. Lowdon Bros., electrical engineers, of Dundee, were the contractors.

Worthing.—The resident engineer's last report states that the number of applications is 264, of which 245 have been connected, that the number of 8-c.p. lamps applied for was 15,755, and that the number connected was 15,025. Various extensions of the mains were recommended. The receipts for the first six weeks of the present quarter were £791, as against £538 for the corresponding six weeks in 1902, or an advance of £253. On the other hand, the expenditure, including capital account charges, was £665, as against £588 for the corresponding six weeks last year. This year, as compared with last year, therefore shows a net profit of £176.

Bristol Channel Telephones.—The telephonic connection between lighthouses and the shore in the Bristol Channel has been extended by Braunton lighthouse and Braunton village being "wired"; the post office there is to be also switched on when necessary to the telephone wire connecting Appledore and Croyde coastguard station. The lighthouse keepers in the Bristol Channel will now be in a position to communicate direct with the several coastguard stations, and in this way much valuable time will be saved in coming into touch with ships in distress. Previously, in the case of Braunton lighthouse notifying to Braunton to communicate with other places, a foot messenger had to be employed.

Buenos Ayres.—In reference to the Buenos Ayres municipal lighting scheme and to the proposed loan of 16,000,000dol. gold, which sum is to be applied in the carrying out of the works, the municipality has received an offer on behalf of London bankers by the Corporacion Comercial Sud-Americana for an issue of the sum named, in bonds, bearing 6 per cent. interest and amortisation of 1 per cent., the issue price to be fixed at 85. The directors of the company are Messrs. J. S. Dillon, M. G. Fortune (of Fortune and Moncrieff), J. Etchegaray (general manager of La Acumulativa Savings Bank), W. C. Hoard, and W. T. Damon (legal representative of the Bahia Blanca and North-Western Railway Company).

Arcs on Tramway Poles.—We are informed that the Gilbert Arc Lamp Company have, as sub-contractors to Callender's Cable and Construction Company, Limited, designed and supplied the arc lighting equipment for Batley, Yorks. An interesting feature is the use of the Gilbert Arc Lamp Company's raising and lowering gear on the tramway poles, for which special boxes and winches had to be designed. The steel cord is carried up the outside of the post in ⅜in. pipe from the combined winch and gear box, which allows for the necessary lateral notion of the cord, and the whole has been so contrived that it is quite neat and unobtrusive. Messrs. Lacey and Sillar are the consulting engineers.

Leicester.—The Guardians have adopted a report from the North Evington Land Committee with regard to the heating and lighting of the new infirmary, recommending that the recent resolution adopting a scheme for the private supply of electricity be rescinded, and that the current be conducted from the cables of the Corporation. It was pointed out that the Corporation could supply the new building with electricity for lighting purposes at a much cheaper rate than the Board could manufacture a private supply. The cost of the Corporation supply would be about £425 annually, while the buildings and machinery for a private supply would entail an initial outlay of £7,000 or £8,000, without taking into account the cost of coal, oil, and labour.

Pitlochry.—At a recent public meeting to consider whether an installation of electric light for the district should take place it was explained that, provided the consent of the proprietors concerned could be obtained, a private company proposed to utilise the Falls of Tummel for the motive power; that the necessary 2½ miles of cable would be laid to Pitlochry—underground, so as not to interfere with the scenery—and that, further, wires would be put into houses and shops free of charge, the owners supplying the requisite fittings and lamps. The cost was given at an equivalent to a gas rate of about 3s. 3d. The company were also prepared to light the streets on the same terms. Should Pitlochry become a burgh, the community would have the option of purchasing the undertaking at certain times on certain conditions. The meeting approved of the scheme, and instructed the local District Committee to act in their interests, but without incurring any financial obligation.

Hornsey.—The Highways and Lighting Committee have received a letter from the General Post Office stating: "I am directed by the Postmaster-General to say that the question of extending the Post Office London telephone system to Hornsey has already been under his consideration, with the result that it has been decided to open an exchange at Crouch End, to serve the Crouch End, Hornsey, Highgate, and Muswell neighbourhoods, as soon as the districts now in hand have been dealt with. The Postmaster-General regrets, however, that he is not yet in a position to say when it will be possible to open the exchange. The extension of the Post Office London telephone system to the outlying districts of the London area can only be taken in hand after the more pressing needs of inner London have been met, and although it is hoped to begin operations in Crouch End early next year, a considerable time will necessarily be occupied in completing the underground system which it is proposed to provide, and in constructing and equipping the proposed exchange." Another letter is to be addressed to the Postmaster-General urging more prompt attention to the matter.

Brighton.—The year's income on the revenue account of the electricity works was £82,392. 19s. 10d., made up of the following items: electricity sales, £58,033. 4s. 6d.; public lamps supply, £10,351. 17s. 5d.; tramways electricity supply (November to March), £9,218. 6s. 3d.; meter rents and sundries, £4,789. 11s 8d. The expenditure came to £47,208. 13s. 11d., the chief items of which were: £20,432. 12s. 1d. for coal, £6,265. 14s. 4d. for wages at works, £2,492. 0s. 8d. for repairs and maintenance of machinery and plant, £4,295. 12s. 7d. on public lamps, and £3,466. 17s. 3d. under the head of salaries. This left a balance of £35,184. 5s. 11d. to be transferred to the net revenue account. Here interest and sinking fund charges accounted for £27,199. 12s. 2d., leaving £7,984. 13s. 9d. as the net profit to be carried to the next account. The capital account shows that the total expenditure up to the beginning of the year had been £404,858. 16s. 5d., and this was increased during the year to £463,764. 7s. 6d., the principal items being £30,675 on account of the new generating station at Southwick, £9,887. 9s. 10d. for machinery and plant, and £11,461. 0s. 3d. for mains.

Aberdeen Telephones.—We understand that the negotiations between the sub-committees of the Streets and Roads and Finance Committees of the Town Council and Mr. Gaine, manager of the National Telephone Company, have broken down, but the committee has yet to report to the Council. It appears that the Telephone Company were prepared to expend £60,000 on an underground system in the town, and to allow the Corporation to undertake all the work, under the superintendence of the city's engineer, and would pay all the costs. The committees, however, before allowing the company the privilege of opening their streets, wished to get a cheaper rate for the subscribers than the present sum of £8. 10s. They were anxious that the subscribers should get an unrestricted service for £7. It was pointed out to the committee that £8. 10s. was a cheaper rate than that given in most other cities in the United Kingdom, and as the Telephone Company had only a license from the Postmaster-General up to 1911, it would not pay the company to give a cheaper rate. They were prepared, however, to give other facilities—to introduce what was called the omnibus rate. For large groups of subscribers the rate would be 25s. for 600 calls per annum, and ½d. per call afterwards. Different groups were then dealt with, when it transpired that four subscribers on one wire would get a service at the rate of £4 per annum, and two subscribers at £6. The committee decided to recommend the Council not to accept these terms, whereupon, it is reported, Mr. Gaine withdrew his offer. There are about 1,800 subscribers on the Aberdeen section of the telephone.

Chesterfield.—The Town Council have adopted the estimate of the electrical engineer (Mr. Acland) for an extension of the works at a cost of £5,680. The extensions are made necessary by the continually growing demand for current. On the corresponding Saturday last year the maximum turn-out on the feeders was 266 kw., while last Saturday they turned out 325. Mr. Acland estimates that the Council might soon expect it to be 350. The units generated on the Saturday in 1902 were 1,919 and this year 2,774. The units sold in November last year were 31,000, while this year they were 50,000 in round figures, which showed the great advance made at the station. The total sales in units for the year ending last March came to 209,000, while this year, Mr. Acland estimated, they would amount to 350,000. In the ordinary course of things, if they had not had to consider the tramways, they would probably have recommended the provision of a 200-kw. extra plant—always striving to keep 200 kw. ahead. Seeing that they had the trams as now proposed, they had decided to recommend putting down a 400-kw. plant, and it was a great deal cheaper per kilowatt to put down that than a 200-kw. plant. Earlier in the year he was asked if they would require further plant for the tramways, and he then stated that they would not for the present line, which would take about 100 kw.; but, of course, that was all altered now, and that was why they had to say that other plant would be required. They were now proposing to run the tramway from the top end of Brampton right away to Whittington Moor. It was also proposed to combine Nos. 1 and 2 dynamos at a small cost. If they put down the proposed plant, the plant at the station would be 1,000 kw., and would have cost them about £50,000, which worked out at £50 per kilowatt.

Blairgowrie Telephones.—Mr. W. F. M'Alpine some time ago was negotiating with the National Telephone Company for the introduction of telephones into Blairgowrie, Rattray, and Coupar Angus.

Digitized by Google

The company could not get the permission of the Post Office authorities to use the trunk line in connection with Blairgowrie. Mr. M'Alpine forthwith applied to the secretary of the General Post Office, London, who was willing to accede to the request. It would be necessary to erect a circuit from Dundee or Perth, for the cost of which they require a guarantee calculated at the rate of £5 per annum per mile of line in respect of fees for trunk calls. The circuit could be carried by way of Coupar Angus, which could share in the guarantee. The charge for communication between Coupar Angus or Blairgowrie and Dundee or Perth would be 3d. for each three minutes' conversation. The rates for a connection with an exchange within half a mile of subscribers' premises would be £3 per annum, which includes cost of instrument, with message fees as follows: 1d. for each local call originated over the circuit up to 1,500; ½d. from 1,501 to 3,000; and ¼d. from 3,001 and upwards; the minimum yearly amount payable by each subscriber for messages, 30s. The rates would cover communication between Post Office subscribers at Blairgowrie and Coupar Angus, and subscribers would be entitled on payment of the appropriate trunk fee to communicate with all towns of the United Kingdom connected with the trunk system. Subscribers could use their circuits to forward messages to the Post Office for onward transmission as telegrams, etc. The charge for use of call office for local calls is 1d. for each three minutes' conversation. The proposal has received such cordial support that Mr. M'Alpine is quite confident that the required number of subscribers will be forthcoming. Were the project once matured into concrete form 60 is not too many to anticipate. At Alyth, it is understood, the National Telephone Company failed to induce the requisite number of subscribers to come forward. The terms offered by the Post Office may induce that burgh to join in the circuit if the line be between Dundee and Blairgowrie, which is probable.

PROVISIONAL PATENTS, 1903.

Nov. 30.

26074. Improvements in sound-conveying apparatus applicable to speaking tubes, telephones, and phonographs. Inez Belle Hogan, 27, Chancery-lane, London.

26082. Means for automatically preventing the speed of electric cars from exceeding any predetermined limit. E. F. Kent and F. Rogers, 17, Causeway, Cambridge.

26083. Improvements in electric furnaces. William Cardno and Joseph George Dalton, Dunmore, Kirkhill, Cambuslang.

26124. Improvements in apparatus for controlling and operating the points of electric railways and tramways. Thomas Bell Stewart, William Herbert Turner, and Rowland Edward Dixon, 8, Quality-court, Chancery-lane, London.

26144. Electromagnetically-operated apparatus for controlling the inlet devices of steam and gas turbines. Theodor Reuter, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26165. Improvements in electrical elevators. Rudolph Charles Smith, 55, Chancery-lane, London.

26170. Improvements in or relating to electric switches or controllers and magnetic blow-outs employed therewith. Philip Kirkup and William Alderson, 70, Chancery-lane, London.

26174. Improvements in couplings for electric cables. Franklin Wise Howorth, 46, Lincoln's-inn-fields, London. (Franklin Everhart and John Dossert, United States.) (Complete specification.)

26180. Improvements in electric fuses. Alexander Hepke and Heinrich Ascher, Norfolk House, Norfolk-street, Strand, London.

Dec. 1.

26185. A new or improved adaptation of electric bells to musical purposes. John Howarth, Commercial-street, Halifax.

26200. Improved electric generator. David Burns and James Macarthur Fleming, 37, West Nile-street, Glasgow.

26208. J. E. Jaggar's cover for electric tramcars and others. Joseph Ernest Jaggar, 6, Granby-grove, St. Michael's-road, Headingley, Leeds.

26211. Multiplex telephony. Wallace Fairweather, 65, Chancery-lane, London. (Willard M. Miner, United States.) (Complete specification.)

26230. Improvements in or relating to combined trolley arm and brake controllers for electric tramcars. International Trolley Controller Company and James Kynoch, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26241. Improvements in electrodes for secondary batteries. Henry Leitner, Lynton, Dartnell's-park, Byfleet.

26242. Improvements relating to telphers partly applicable also to vehicles propelled electrically from a distance. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (The United Telepherage Company, United States.) (Complete specification.)

26247. Improvements in and relating to electrically-operated driving mechanism for centrifugal machines. William L. D'Olier, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26248. Improvements in telephone transmitters. Philip Green Randall, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26255. Improvements in attachments to desk telephone instruments. Henderson Pierce Childress and Nathaniel Miles Sauls, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26259. Improvements in apparatus or means for regulating or governing the speed of engines employed in driving electric current generators. James Yate Johnson, 47, Lincoln's-inn-fields, London. (The Elektrizitäts-Aktien-Gesellschaft vormals W. Lahmeyer und Co., Germany). (Complete specification.)

26261. Improvements in or relating to magneto-electric igniting devices for internal-combustion engines. Camille Bailly, 111, Hatton-garden, London. (Complete specification.)

26264. Improvements in or connected with mechanism for electrically winding up springs or weights. Edward Du Bois, Norfolk House, Norfolk-street, Strand, London.

26267. Improvements in and relating to electric measuring and recording devices. Claude William Atkinson, 1, Queen Victoria-street, London.

26268. Improvements in and relating to electrolytic meters. Claude William Atkinson, 1, Queen Victoria-street, London.

26269. Improvements in or relating to switches for electric currents. William Phillips Thompson, 322, High Holborn, London. (Hermann Schor, France.)

26271. Improvements in cohering receivers used in space telegraphy. Frank Emuel Peters, 6, Lord-street, Liverpool. (Complete specification.)

26273. Improvements in controlling devices for electric motors. Gustavus Adolphus Edward Kohler, 46, Lincoln's-inn-fields, London. (Complete specification.)

26274. Improvements in means for ventilating electrical machines. The Actiengesellschaft Brown, Boveri, et Cie., 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Dec. 16, 1902, being date of application in Swizerland.) (Complete specification.)

26276. Improvements in or relating to electricity meters. William Geipel and Frederick Montague Townshend Lange, 46, Lincoln's-inn-fields, London.

26291. Safe and improved method of attaching detonators-caps, or exploders to fuse tape, or electric wires, making the same water and air tight. William Henery Edwards, 79, Pitt-street, Sydney, New South Wales.

Dec. 2.

26307. An improved electrical connection for electro-chemical apparatus. Frederick James Turquand and John Frederick Wakelin, 5, Tottenham-street, London.

26352. Improvements in or relating to vacuum arc lamps with external air-cushioned regulating device. Hubert Emonds, 5, Hatton-garden, London. (Complete specification.)

26372. Improvement connected with cells for storage and other batteries. Henry Soar and William Holloway Fellows, 173, Fleet-street, London.

26378. Improvements in and means for effecting the regulation of asynchronous alternating or three-phase current electric motors. James Yate Johnson, 47, Lincoln's-inn-fields, London. (The Elektrizitäts-Aktien-Gesellschaft vormals W. Lahmeyer und Co., Germany.) (Complete specification.)

26380. Improvements in safety fuses for electric circuits. James Yate Johnson, 47, Lincoln's-inn-fields, London. (The Elektrizitäts-Aktien-Gesellschaft vormals W. Lahmeyer und Co., Germany.) (Complete specification.)

Dec. 3.

26427. Improvements in electromagnetic controlling gear for electric arc lamps, electric circuit breakers, and the like automatic mechanism. August Ecksteln and Arthur Ernest Angold, Peel Works, Adelphi, Salford, Manchester.

26435. Improvements relating to electrically-actuated mechanism. Louis Jacot, 18, Southampton-buildings, Chancery-lane, London.

26449. A new form of ammeter and voltmeter. William James Bell, 15, Vanbrugh Park-road, Blackheath, London.

26455. Improvements in and relating to elastic fluid turbines. The Warwick Machinery Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26456. Improvements in insulated electric conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26457. Improvements in insulated coils for electrical apparatus and process of making the same. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26458. Improvements in insulating electric conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Digitized by Google

26459. Improvements in brake systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26460. Improvements in electric rheostats. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26461. Improvements relating to rotary electric converters. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26462. Improvements in electric arc lamps. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26463. Improvements in and relating to air-brake systems and valves therefor. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26464. Improvements in static influence electrical machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26465. Improvements in systems of electric motor control. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26476. Improvements in or relating to electric incandescent lamps. Percy Joseph Handford Driscoll and Harry Sleeman, 322, High Holborn, London.

26488. Improvements in and relating to electrical ignition apparatus. Montague Stanley Napier, 18, Southampton-buildings, Chancery-lane, London.

DEC. 4.

26513. An improved canopy trolley for electric tramcars driven on the overhead systems. Joaquim Antonio de Macedo, Leventhorpe Hall, Swillington, Yorks.

26533. Electric heaters and improvements relating thereto. William Krause, 70B, Rye-lane, Peckham, London.

26537. An improved conduit for containing electric cables and wires and pipes and tubes and the like. W. Hepworth-Collins, 17, Nicholas-street, Manchester.

26538. An improved conduit for containing electric cables and wires and other wires, tubes, and the like, primarily intended to be carried along thoroughfares. W. Hepworth-Collins, 17, Nicholas-street, Manchester.

26553. Improvements in or connected with apparatus for electrically igniting miners' safety lamp. William Best, Albert Best, and Robert Octavius Best, 33, Chancery-lane, London.

26577. Improvements relating to field magnets for electrical machines. Georgio Finzi, 45, Southampton-buildings, Chancery-lane, London.

26589. Improvements in incandescent electric lamps. August Bourdos and Henry Cecil William Gibson, 24, Southampton-buildings, Chancery-lane, London.

26595. Electric igniting apparatus. Konrad Schaffler (*recte* Glössl) and Emanuel Jilck, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

DEC. 5.

26603. Improvement on electric motors and dynamos. Hans Faerber, "Hillside," Lower Weston, Bath.

26607. A new combined electric switch, wall socket, and plug. Herbert Robertson, 7, Leamington-terrace, Edinburgh.

26618. A mechanical switch for electric installation of motor cycles. Ralph Child Meredith, Urswick, Maryvale-road, Bourneville, near Birmingham.

26659. Improvements in magneto-electric ignition devices for internal-combustion engines. Paul Masson, 111, Hatton-garden, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 24, 1903.

1902.

24013. Attachment of carbon filaments in incandescent electric lamps. Fanta and Butler.

26386. Electrical synchronism indicating apparatus. British Thomson-Houston Company, Limited, Clinker, and Wedmore.

26416. Railway and tramway points operated by or from the vehicles and points or switches for use upon overhead conductors of electric railways and tramways furnished with points. Zylberlast.

26640. Electrical apparatus for automatically actuating signals on and stopping railway engines and trains. Gerstmann.

26870. Alternating-current motor. Deri.

26970. Electrical apparatus for registering the discharge of liquids by pumps. Liquid (Electric) Register Syndicate, Limited, and Cassal.

27322. Electric switches. Pieper.

28858. Electric rheostats. Pieper.

1903.

159. Electrically-operated bells. Barber and Larmuth.

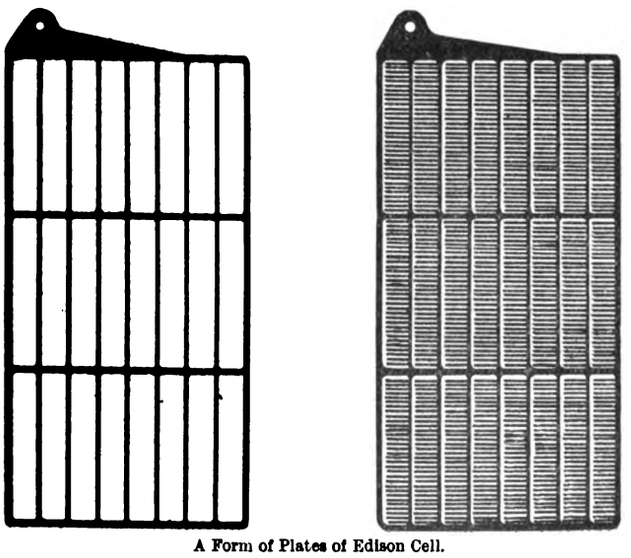
THE EDISON ACCUMULATOR FOR AUTOMOBILES.*

BY W. HIBBERT, ASSOCIATE-MEMBER.

The problem of making an accumulator with an alkaline electrolyte has been before the world for many years, and has been attacked by a fairly numerous body of workers. It is known that Mr. Edison is one of this number, and various public statements have appeared as to the results of his labour. Most of these can be neglected as void of authority, but the account published by Dr. Kennelly before the America Institute of Electrical Engineers was evidently based on carefully executed work. From this paper we learned the general nature of the cell, together with certain useful numerical data. Fourteen watt-hours were obtained from 1lb. weight of the cell, the average E.M.F. being about 1·25 volts. It is not necessary to repeat here the other data from Dr. Kennelly's paper, as they will be brought up to date by the facts to be quoted from my own tests. It is sufficient to say that very little was done during the next year. The matter seemed to fall into the background, and public opinion settled down to a vague belief that the cell had not yet reached the commercial stage. Indeed, I have heard doubts expressed as to the very existence of the cell. To some extent I shared this scepticism, not because I doubted the existence of the accumulator, but because of its constitution. I doubted (and expressed my doubts in print) whether the plates would be altogether free from local action, and whether a very small amount of this weakness would not be sufficient to destroy the plate. These fears were based on the data afforded by Dr. Kennelly's paper, more especially the thinness of the plates, and also the probable results of mixing graphite with the active material. Such anticipations were, I suppose, quite legitimate as anticipations, but they have not been justified by the results of actual trial. It is one of the striking features of the cell that it recommends itself by work more than can be done by any verbal account.



A Form of Plates of Edison Cell.

In the early part of this year I obtained three of Mr. Edison's cells of small size, and in early June was provided with a standard automobile cell. Finally, during part of my summer vocation I was able to run about 500 miles on an automobile driven by 38 Edison cells. The general results of the work done on all these will be described in this paper. I shall confine myself to a somewhat simple statement of the facts verified by myself, feeling sure that these will be most acceptable to the members of the Institute. But it may be worth while mentioning that well-known men at Milan, Paris, etc., have obtained laboratory results which agree in all the main particulars with my own. They have not as yet had the opportunity of testing on the road. A brief description of the cell will be advantageous.

Standard Automobile Cell.—This contains 14 positive and 14 negative plates. Each plate is made of sheet steel, nickel plated, punched with 18 holes of rectangular shape. In each of these holes is inserted a flat pouch or pocket containing the compressed active material. The walls of these pockets are perforated by exceedingly fine slots or holes, through which the liquid can penetrate. Thus the current can easily pass to and from the active material contained in the pockets.

Active Materials.—Both positive and negative plates are alike, except in respect of the active material. The pockets on the positive plate contain nickel peroxide; those on the negative plate contain finely divided iron. Each of these active materials is, I understand, mixed with flake graphite.

Electrolyte.—The liquid is a 20 per cent. solution of potash.

Arrangement.—The plates are fixed very near each other. Yet there does not seem to be any danger of short-circuits. The plates are thin, it is true, but being made of steel, they are thick enough to give rigidity. As a further precaution, vulcanised-rubber separators are put between the plates, making the whole a compact mass, whose stability is calculated to resist all the ordinary mechanical shocks it is likely to undergo.

External Arrangements.—The cell is sealed in its steel case, the top being fixed on by a special solder not acted on by the potash. Two stout connecting pins (from the positive and negative plates respectively) come through liquid-tight bushes of vulcanised rubber. These pins are made slightly conical, as are also the connectors which fit on them, and the mechanical finish and easy grip of this terminal add to the value of the battery. The connector is further secured by a screw nut and fastening pin. The connector has a much higher conductivity than those of the ordinary type of accumulators. On the top of the case there are also (*a*) a spring stopper with rubber flange, covering the hole by which the electrolyte is introduced or distilled water added from time to time; (*b*) a venthole guarded by a gravity valve. This provides for the escape of the gas evolved during charge. The hole and valve are covered by a gauze nipple, which prevents escape of spray while allowing gas to pass. It also prevents any flame finding access to the interior of the cell through the stream of evolved gas.

The complete cell stands 13in. high (over all), and measures 5·1in. by 3·5in. horizontally. It weighs 17·8lb. A large part of the external steel case is corrugated to increase its rigidity. An immediate consequence of examining these features of the cell is to impress the observer with their admirable fitness—perfection is hardly too strong a word. That which is so lacking in ordinary accumulators—mechanical strength or design—is here in obvious and large measure. The general mechanical

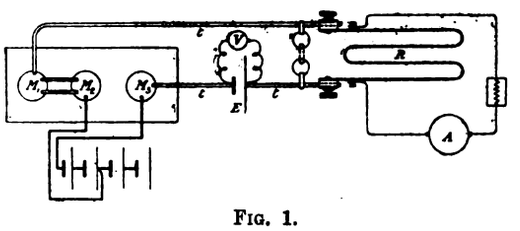


FIG. 1.

structure of the cell is well calculated to remove or to diminish any antecedent adverse opinion.

Electrical Data.—The E.M.F. is 1·33, though, as there is a very persistent gaseous polarisation effect, the figure cannot be regarded as quite rigid. For a long time after charging it is much higher. The internal resistance is 0·0013 ohm. The output at 60 amperes is 210 watt-hours = 11·8 watt-hours per pound. The diagram (Fig. 1) shows the arrangements used for charging and discharging. E is the cell under test; *t t t*, pieces of trolley wire used for connections; M_1, M_2, M_3, mercury cups standing in a large tank full of oil; R, a standard resistance = 0·01009 ohm, verified by the Board of Trade; V and A, voltmeter and ammeter, both recalibrated for these experiments. Large lead accumulators were used for charging E. For the purpose of charging, constantan resistances of varying value and diameter were used to bridge M_1 M_2. For discharging, it was necessary to bridge M_2 M_3 as well. The control of

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

either strong or weak currents was quite easy and rapid by putting constantan wires in parallel across the mercury cups. In very few of the experiments did the current vary as much as 1 per cent. The average variation was probably about 0·3 or 0·4 per cent. The curves in Fig. 2 tell their own story. A striking feature of the curves is the relatively high value of the capacity at the higher discharge rates. The difference in ampere-hours at 30 and 60 amperes is almost negligible. Even at 120 amperes the capacity is 93 per cent. of the maximum, and at 200 amperes is still as high as 82 per cent. These results at once indicate a valuable feature of the cell for many of the emergencies of engineering. That the quantity obtainable at the high rates should be such a large proportion of that possible at low rates is both surprising and agreeable.

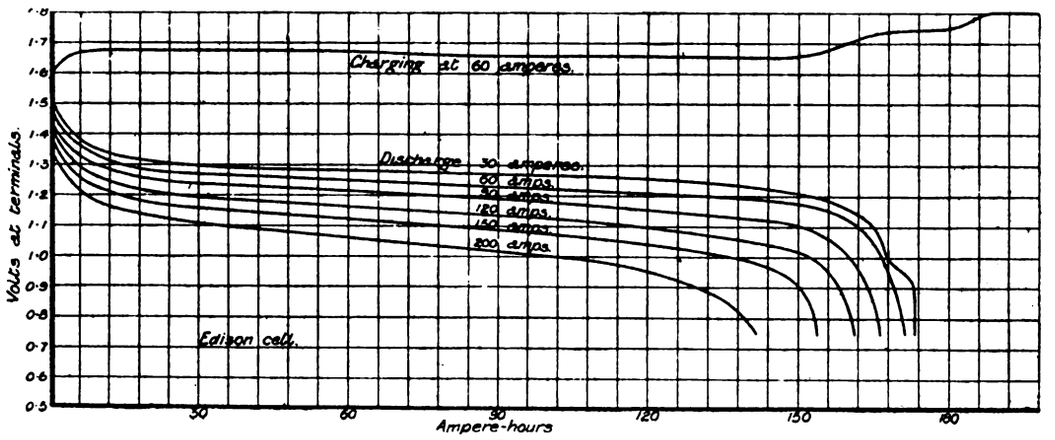

FIG. 2.

Output.—In relation to the weight of the cell the work done is higher than usual. Taking the output at 210 watt-hours,* and the weight at 17·8lb., the specific output amounts to 11·8 watt-hours per pound of cell. This must be regarded as a high figure. It is true that nearly equal figures have been obtained with other cells, but confessedly at considerable risk. The weight of lead cells is reduced by making the supports very thin, but this shortens life. Output can be increased by using stronger acid, but this leads to rapid loss of charge if the cell stands idle. These serious risks do not accompany the method of getting high specific output in the case of the Edison cell. It is, as we shall see, able to retain a large proportion of its charge for a long time, and its relation to "life," although not yet fully verified by my work, is one of very considerable security as far as can be judged by the results already obtained. In relation to volume, the specific output is 88 watt-hours per cubic foot.

Influence of Temperature on Output—In the case of lead cells this is very marked. With the Edison cell no definite series of experiments has been made, but accidental circumstances afford evidence of some interest. Some discharges were taken on two of the few very hot days of last summer. The high temperature of the air, added to the heating effect of the currents, caused the temperature of the cell to rise very high. With a current of 150 amperes it reached 54deg. C. The output rose to 163 ampere-hours, some nine ampere-hours more than were obtained at a temperature of 33deg. This is an increase of 5·5 per cent. in capacity for a rise of 21deg., or an increase of 0·26 per cent. per 1deg. rise.

Other experiments, not specially designed to test the point, indicated a detectable but small increase. The effect is, however, very much less than with the lead cell. With them it may be 2 or 3 per cent. per degree Centigrade. With the Edison cell, a few degrees difference in temperature would produce hardly any change in the quantity output. This difference in the effect of temperature doubtless arises from the difference in the nature of the actions going on in the respective electrolytes. The continued working of the lead cell demands a continued supply of the acid at the internal working faces of the porous materials on the plates, and a rise of temperature helps to provide this by increasing the rate of diffusion of acid from the outside. In the Edison cell there appears to be practically no need for diffusion or circulation of the liquid. It is not an active material in the ordinary sense; it acts only as a conductor. Hence a higher temperature cannot change the action except by diminishing the internal resistance of the cell. Even here the action must be differential. For the liquid will diminish in resistance as the temperature goes up, while that of the plates themselves will increase. The first of these, however, being the greater, will determine the resultant change, with a consequent increase in chemical action before the pressure falls to a limiting value. For example, in the experiment described, which led to a final temperature of 54deg. C., the resistance of the electrolyte would be about 30 or 40 per cent. less than in the corresponding experiment at 33deg. It is also of interest to note that these experiments at higher temperatures were the earliest. The other experiments described in this paper were all done subsequently, and therefore show that no injury had resulted from the heating due to higher external temperature and also to the excessive currents passing through the cell.

* This is at 60 amperes; at 30 amperes the output is somewhat higher.

INTERNAL RESISTANCE.

It is not easy to determine this except at times when the pressure curve is tolerably flat. Attempts were made, however, to get an approximation by opening the circuit for a moment or two and noting the rise in volts at the terminals. The value $\frac{E-V}{C}$ comes out as a tolerably constant figure from the various curves in Fig. 2. It rises from 0·0013 ohm with the lower currents to 0·0016 with the higher. The value does not vary appreciably over the greater part of the discharge. But towards the end, where the pressure begins to fall quickly, the resistance rises at a fairly rapid rate. At the end it may approach 0·004 or 0·005 ohm.

SHORT-CIRCUIT.

With the object of testing the power of recovery, one of the small cells was partially discharged, and then short-circuited for 48 hours. After a subsequent long charge it gave the discharge curve, B (Fig. 3). Compared with

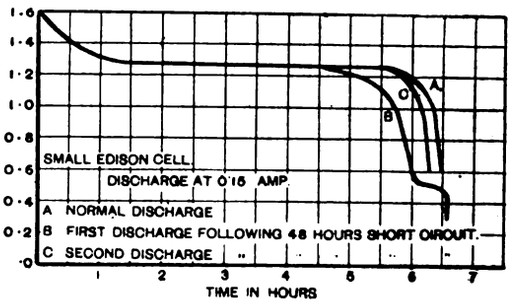

FIG. 3.

the normal discharge curve, A, B indicates a deficiency. It is evident that the cell has not yet recovered. On charging again, however, and taking a second discharge (curve C), the deficit hardly appears; the cell has

Digitized by Google

practically recovered from the harsh treatment to which it had been subjected.

High Rate of Charging.

The foregoing experiments prove conclusively that the Edison cell can maintain a high rate of discharge. The interest of this question hangs on its maximum charging rate, and this I have not been able to reach. The following curves (Fig. 4) show the course of an experiment made to test this point. The cell was first carefully discharged at 30 amperes down to 0·75 volt. It was then charged for one hour, 177 ampere-hours being put in. The current was not quite steady, varying from 180 to 176 amperes over most of the time. Near the close of the hour it fell to 166 amperes. The subsequent discharge shows that 124 ampere-hours were delivered, which equals 70 per cent. of the charge. Further experiments on this point appear in the later section dealing with the

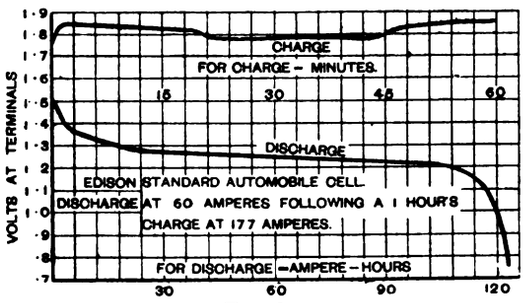

Fig. 4.

motorcar work, proving that the cell can be charged at over 200 amperes.

Flexibility of the Cell.

The new cell will probably be called upon to stand very rapid and large fluctuations in the value of the current. The following curve (Fig. 5) shows that it behaves like an elastic structure, its pressure rising and falling with varying demand, but responding at such a rapid rate that the lines of changing pressure appear vertical on the diagram. The change to and from 230 amperes will appear more trying if the weight of the cell be kept in view.

Continued Discharge at Lower Voltage.

In most of the experiments so far described the discharge was stopped when the terminal voltage fell to 0·75. At this point, as all the curves show, the pressure is falling rapidly, and would lead to the assumption that it must speedily reach zero. But this is not the case. At

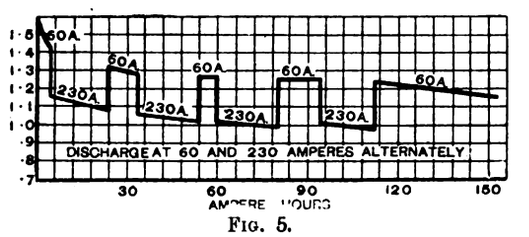

Fig. 5.

a still lower pressure the rate of fall suddenly alters, and the curve becomes flat again. Presumably this is due to a secondary chemical action arising when the active materials have been more or less changed by the ordinary discharge. The curves given below (Fig. 6) indicate the extent and variation of this prolonged discharge. They were given by one of the small cells containing four pockets—two positive and two negative. The currents are small, but the indications are typical of the behaviour of larger cells.

Effect of Rest.

There are many experiments in my notebook which show that the cell does not suffer when allowed to stand discharged for fair lengths of time. A very good illustration will be given when dealing with the motorcar trials. A parallel question arises as to how far the cell can retain its charge when allowed to stand idle. Various trials have been made, two of which may be mentioned. A cell was charged fully, and allowed to stand 48 hours before discharge began It then yielded 155 ampere-hours = 91 per cent. of the full discharge. Part of this deficiency is undoubtedly due to the fact that a discharge commencing immediately is enriched by the gases contained in the pockets along with the active material. The experiment just alluded to was, therefore, regarded as giving an idea of the immediate value of this gas effect, along with the 48 hours' action due to a short rest, such as the experiment was intended to detect. To get a better estimate of the effect of rest on the active materials, the cell was now charged up again and allowed to rest for 26 days. The discharge which followed gave 124 ampere-hours. Com-

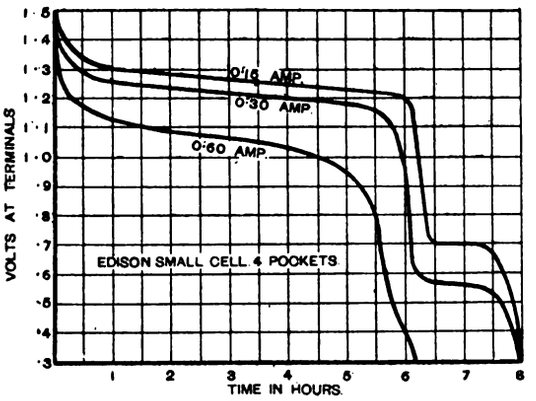

Fig. 6.

pared with the full discharge—170 ampere-hours—this is equal to 73 per cent. But compared with the discharge taken after two days' rest, we have an efficiency of 80 per cent. after 24 days' rest. That is to say, the active material lost only 20 per cent. of its charge in 24 days. The reference here made to the effect of rest on a charged cell makes this a convenient place to say how persistent is the effect of the electrolytic gases on the E.M.F. When charging is complete the E.M.F. is about 1·6 volts, and if the cell be left on open circuit the value falls very slowly to about 1·35. It may be interesting to give a curve showing the time change in the E.M.F. when the charged cell is allowed to stand.

Efficiency.

Efficiency is not very much considered in the present methods of working traction cells. A laboratory experiment is of much less use on this point than on many others. The strength of acid employed enjoins on the user the advisability of charging up when the car comes in, and of giving the cells a "buck-up" charge if much time elapses before the car is used again. This reduces efficiency.

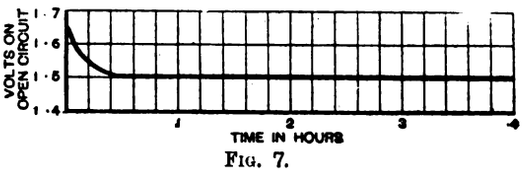

Fig. 7.

Tested on the bench, the Edison automobile cell has an efficiency varying from 66 to 50 per cent. Charged and discharged at 60 amperes, I found it to be just about 60 per cent. Charged at 100 amperes and discharged at 60, the efficiency was 56 per cent. Charged for one hour at 177-ampere rate and discharged at 60 amperes, the efficiency was 50 per cent. The highest figure (about 66 per cent.) was obtained at 30 amperes. These figures are lower than would be found with good lead traction cells under the same condition of discharge following immediately after charge; but the experiment before described, in which a cell was kept charged for nearly four weeks, proves that under garage conditions the Edison cell would have a much higher efficiency than the cells now used. The point is of secondary importance only, as the total cost of keeping a car in running order is so high in relation to the cost of energy that variations in the latter are of small moment.

Observations on the Road.

In considering the conclusions which could legitimately be drawn from the foregoing laboratory experiments, it was obvious that the results might be objected to on the ground that an accumulator intended for automobiles ought to do its work on the road, subject to all the irregular vibration which travelling entails. The force of this objection is obvious, and I was anxious to get some chance of watching the battery under running conditions. Fortunately, some 40 cells arrived from America in July last, and Mr. Dick had 38 of these placed on a runabout, and gave me the chance of observing their behaviour. To this opportunity I could devote only a part of my summer holiday, and, therefore, the observations do not cover such a long run as is desirable. But they were long enough and varied enough to show that the laboratory results are still obtained when the work is done on the road. A brief description of the car will suffice. It was a runabout made by the Stadebaker Company, of Indiana, weighing, when fully loaded and carrying two persons, about 1,950lb. Of this 700lb. was due to the 38 cells and their wooden frames. Unfortunately, the battery and motor were unhappily mated, the latter being a Westinghouse 40-volt 24-ampere machine, while the cells gave an average pressure of about 48 volts. The motor was, therefore, overloaded all the time, and if it had been a point of importance to investigate the motor and car as well as the battery some changes would have been necessary, but as the battery could by careful observation be tested independently, and as time was not too plentiful, the car was accepted as it stood. It is not necessary here to describe any of the mechanical details. The controller had four stops with four speeds, but the first and second were hardly ever used except momentarily. It remains now to state the results of the tests. The form in which this is done is of some importance, because it ought to deal with the battery side of the investigation. Traction questions proper are subsidiary. A brief statement will clear them out of the way.

Tractive Effort.—On good level road the speed was close to 14 miles per hour, and the power about 1,920 watts, which is practically equal to 2,200 watts per ton. These figures indicate about 79lb. per ton for the tractive effort. Allowing for the motor efficiency, and putting it at 85 per cent. (probably not so good because of overloading), the tractive effort is 67lb. per ton. The work appears to be about 135 watt-hours per ton-mile, a higher figure than is usually taken in America. This is not astonishing, considering the want of balance between battery and motor.

Cost of Power.—Fourteen miles meant nearly two Board of Trade units. If we take the efficiency of the cells as low as 50 per cent. (it is always low in electric tration as usually carried out), the charging would be four units. At 2d. per unit the cost would be 8d., or 0·57d. per mile. Turning to the battery. The programme I drew up was intended to yield answers to the following questions: (1) Is the capacity of the cell the same when running on the road as when discharging in the laboratory? (2) Will the battery stand excessive discharge rates on the road? (3) Will it take a rapid charge and utilise it on the road? (4) Will it recover after lying discharged for some time? (5) Does the capacity change in any detectable degree by reason of the mechanical agitation? (6) What attention is required? When the car was handed over to me it had already been driven by the battery a distance of about 400 miles. This work was done in Paris, the charging being arranged by M. Gadot. This part of the work, however, I do not describe, the purpose being to exclude all but my own work.

The following is a diary of our runs:

		Miles.
Aug. 29.	Standing discharge: 159 ampere-hours.	
,, 30.	Paris to Versailles and back, through the park of St. Cloud. Good climb. Run about Paris	39
,, 31.	Eighteen miles towards Rouen and back. About Paris	48
Sept. 1. to ,, 4.	Journey to London. Car ran across Paris, then train to Havre; train also from Southampton to Waterloo. Motor overhauled at Niagara Garage, and then finished the discharge by running round London. At Southampton the battery had to be partially discharged through wire.....	29½
,, 5.	London to Northampton, stopping at Dunstable for a partial charge. Part of the discharge was taken next day round about Northampton	77½
Sept. 7.	Northampton to Leicester. One stiff climb at Hopping Hill	32
,, 8.	Partial charge at 100 amperes for 90 minutes = 150 ampere-hours. Leicester out towards Nottingham	
16	miles and back through Loughborough	38
,, 9.	Charge 225 ampere-hours. Repeated yesterday's run with extension. Discharge 150 ampere-hours	
,, 9.	Charged 1 hour 55 minutes, 219 ampere-hours. Repeated the Loughborough run	77
	Last six miles run out next morning..	
,, 10.	One hour's charge, 150 ampere-hours. Same run. Discharge, 107 ampere-hours. (32 miles.)	
,, 10.	Charged 1 hour 20 minutes = 242 ampere-hours, and started off for Northampton. Storm all the way. Wind dead ahead. Most excessive discharge	65
,, 11.	Northampton to London, with partial charge at Dunstable. Run about in London	71
	Allowed to stand discharged for 10 days.	
,, 20.	Charged for one hour. 186 ampere-hours. Run round London	31
,, 29.	Standing discharge: 158 ampere-hours.	

The total distance run is 508 miles while under my control. Adding the 400 miles run before that time gives 908 miles. It will be observed that several runs were made from Leicester. This was due to the fact that Mr. Hales, the engineer to Mr. Wathes, was kind enough to arrange that he would be ready to assist in charging just as I liked, and at any hour. Mr. Hales also chose for me the route followed, my request being that it should be a fairly typical English road. The conditions of each run were decided not by the desire to make so many miles, but to solve one of the six questions already mentioned.

1. Is the capacity on the road equal to that found in the laboratory? In order to answer this and some other questions, I determined to eliminate the influence of car and motor, and to record observations of voltmeter and ammeter while discharging, just as is done in the laboratory. It seemed to me that the trouble involved (travelling with watch and note-book in hand) was worth facing, and it certainly taught me a great deal which could not have been definitely known in any other way. As will be seen in the Section 5, a preliminary experiment proved that the battery had a capacity of 159 ampere-hours at 60 amperes.* The question was, would the same quantity be available on the road? From the many observations, I choose the record of Sept. 9 as one of those most closely watched. The run was from Leicester to some miles beyond Loughborough and back, with a final run round Bradgate Park-road; distance = 40 miles. Eighty observations of current during the 3½ hours make the ampere-hours 150. As the discharge was not then quite complete—the volts being above 0·75 per cell—it is evident that the quantity delivered in one complete discharge was practically the same as that found in the laboratory.

2. Will the battery stand excessive discharge rates on the road? The original intention was to allow this to be determined by choosing stiff gradients for the car to negotiate. Accidentally, however, and most unpleasantly, we had a better test than that The return journey from Leicester to Northampton was commenced in the afternoon of Sept. 10, the day of the great cyclonic disturbance which spread over England and the West of Europe. That 32-mile run will not easily be forgotten. My ordinary observations were impossible. Recording was a failure; but I mentally noted that the current on the level rose to 55 or 60 amperes instead of 40, the wind being dead ahead and roads greasy. On the slopes the current was frequently 90 and 100, and on one hill the index passed out of my sight, and must, therefore, have been momentarily more than 150 amperes. The journey took four hours, as compared with 2·5 hours on our outward course. The last six or seven miles were covered at a slow pace, and an interesting point crops up in that connection. Although I could not make a written note of the instrumental readings, I kept a pretty constant eye on the ammeter. While these data were fresh in my mind I calculated the discharge from the cells, and made it close to 190 ampere-hours. I regard this as a figure which errs on the side of deficiency rather than excess. If it be asked how this

* This is somewhat lower than I found in the laboratory. Detailed examination of the 38 cells proved that two cells were of decidedly low capacity—probably from the beginning. This would account for the deficit.

Digitized by Google

excessive quantity could be obtained, the answer must be found in that extra delivery at lower voltage. For many purposes this low-pressure discharge is useless, but for an emergency like that of this stormy afternoon it is a great consolation! It helps to carry the car home, although not counted in the normal capacity of the cell. It is noteworthy that the cells deliver the normal current with this lower voltage for quite an appreciable time.

3. Will the battery take a rapid charge (say one hour) and utilise it in discharge? Several experiments of this sort have been recorded. A one hour's charge was tried at Leicester. Unfortunately the supply station belonging to Mr. Wathes was in a state of transition, but his chief engineer, Mr. Hales, took considerable trouble in giving us special facility; 150 amperes was the maximum current we could get at the time, owing to the unfinished state of the new building and machinery. The cells received 150 ampere-hours in the hour, and in the subsequent run delivered 107 ampere-hours = 71 per cent. of the charge. This is exactly the figure found in the laboratory test, and also in the standing discharge test described in (4) and (5). From these three experiments it is clear that with currents of 200, 175, and 150 amperes continued for one hour each, the cell absorbs about 70 per cent. of the charge. I have not had facility for trying a still higher current, but it seems probable that the same proportion would hold good even with a higher current. In Leicester, as in London, the run obtained from a one hour's charge was quite satisfactory.

4. Will the battery recover after standing discharged? The car was run about until its speed, and also the voltmeter, indicated that we were on the final slope of the discharge curves. The car was then allowed to stand 10 days in the discharged condition. At the end of that time it was charged as follows: For 44 minutes at about 200 amperes = 156 ampere-hours; for 16 minutes at about 120 amperes = 30 ampere-hours—total = one hour's charge = 186 ampere-hours. The car was then run round London, and covered 31 miles, yielding 134 ampere-hours. This figure for the discharge was found by numerous observations taken during greater part of the run, combined with less numerous readings for the rest of the time. The efficiency is $\frac{134}{186} = 72$ per cent. From these data it is obvious that the behaviour of the 38 cells after 10 days' idleness in a discharged condition is very similar to that observed in the laboratory when quite new, and also very similar to that observed at Leicester under high charging rate. It was thought that the combination of harsh treatment due to standing discharged followed by excessive charging current would prove specially trying, but the cells behaved very well even under these circumstances. The test now recorded was followed by the final test on capacity as recorded under (5), the two tests taken together giving a decidedly affirmative answer to the question now under discussion. As the question respecting the wisdom of leaving a discharged cell idle is one of great importance, I will make one other remark. No injury appears to arise—the cell works as well after as before. But it is advisable to charge for a longer time after such an idle time. The chemical actions — the absorption changes — are a little slower than usual; or perhaps it is more accurate to say that a greater proportion of active material is in need of restoration by the charge.

5. Does the capacity change in any detectable degree by reason of the mechanical agitations due to running? Accumulators used for automobiles always deteriorate in capacity after a longer or shorter time. Roughly speaking, even a good battery of the lead type shows a diminished capacity after about 600 miles run, even by the crude test of miles per charge. Such a test must always be crude, because of the influence of the road, wind, and gradient on the distance covered, even while the battery is still fresh. As other duties prevented me taking charge of the car for more than 16 days, with no possibility of running anything like 1,000 miles, it was necessary to arrange for an accurate test of capacity at the beginning and end of the trials. A standing discharge was therefore taken at Paris on Aug. 29, and gave 159 ampere-hours. This is slightly less than that found for a single cell in the Polytechnic laboratory, but on examining each cell two were found to be decidedly low, and these two brought down the pressure to the final limit rather prematurely. However, as this figure was to act merely as a standard of comparison for a similar final test, it was accepted, with all the disadvantage of two somewhat inferior cells. On Sept. 29, after running 508 miles, the final standing discharge was taken, and gave 158 ampere-hours. In these experiments the errors of observation may exceed 1, but do not rise to 2 per cent. The result may be regarded as showing that the capacity remained intact during the 500-mile run. Remembering that there were two cells in the 38 which were obviously low—probably from the beginning—it is doing no violence to accept the capacity as normal at the end of my trials, and therefore at the end of something like 900 miles run since they were put on the car. Fig. 8 gives the discharge curve. The observations at Paris and at London

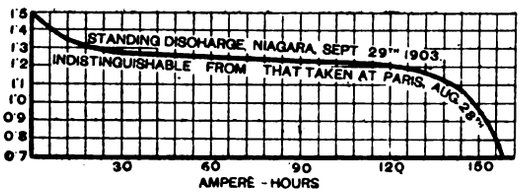

FIG. 8.

are indistinguishable on the scale to which this curve is drawn.

ATTENTION REQUIRED.

To practical men this is a most important point. They have not generally done justice to accumulators, because they have been unwilling to give them that unceasing examination which is devoted to the other parts of their mechanism. If the Edison cells needed more attention than that now given to lead cells, the need would be an objectionable feature to the men who have most to do with them. It was for this reason that I was so anxious to add to my laboratory work a series of trials from the garage point of view. For example, the laboratory could never decide one most simple question. The terminals and connections of the new cell cannot be "burned" in any way comparable with the method adopted for lead cells. Would the mere surface contact and screw nut adopted by Mr. Edison make a lasting connection? Laboratory trials were useless for answering this question, even though it was obvious that the design of the terminal was exceedingly good from the mechanical standpoint. However, my 500 miles on the road were sufficient to test them. Not one of them failed or became weak. Not one of the terminals proper had to be touched from the beginning to the end of the run. We had rough roads and rough weather, so that the motor was seriously overloaded, and the car was so strained that it had to go into serious repair as soon as our run was finished, but the battery and its terminals endured it all. I was especially pleased to see that in the last charge but one, with a charging current of 200 amperes, the contacts were still so good that not one of them became unduly warm. Considering what they had gone through, this was a very good testimonial. Another point about which I had some misgiving, and one that had been mentioned in the American papers, was the question of frothing. It was said that in charging, the evolved gases caused so much frothing that the liquid would soon be run out at the venthole.

During my laboratory experiments, extending over two months' continuous work, frothing occurred on two separate occasions. But on each occasion it lasted for about one minute only. In both cases it occurred at the end of a long charge. On the road frothing occurred with one or two cells on two occasions. Even these did not persist, and their evidence was rather in favour of the result being accidental. It is true that on the Continent I came across a cell which was said to froth rather persistently. But this probably arose from a very simple fact. A workman is very apt to treat the one kind of accumulator as he would the other. I found one of them even using oily

Digitized by Google

waste to polish the cap which covers the vent-hole. It is obvious, however, that many kinds of grease will be objectionable, seeing that with the alkali they readily form soap solution, with a consequent tendency to froth. Soap, grease, and all other colloids ought, of course, to be excluded, and are excluded rigorously from the cell. As the 38 cells on the car were practically free from any degree of frothing worth mentioning, although they were put together by men who had never seen the cell before, and as this agrees with my own experience in the laboratory, I think that the objection made on this ground cannot be substantiated. The point which requires attention, and which cannot be neglected with impunity, is the necessity for adding distilled water from time to time. As far as my own experience went, this was needed after about five or six chargings. This meant after each 160 to 170 miles run with our car. The frequency of the water addition cannot, however, have any settled relation to miles run. It depends on the number of times the cells are charged, and especially if overcharged. As different cars equipped with variable relative weight of battery run different distances on one charge, it is desirable to get this matter put into the right form at once. The men working at garage charging stations are apt to interpret everything in miles.

Life.

Respecting life, there is the general favourable tendency of the evidence already adduced. The cells used in the car had not changed by a detectable percentage of their original capacity at the end of my contact with them. That is the most direct testimony I can offer at present. Chemical examination is proceeding, but has not as yet reached a stage at which I can add to the present knowledge. The chemical changes may be summed up in the following equation:

After charge — After discharge

$$\left\{ NiO_2 \;\middle|\; KHO \;\middle|\; Fe \right\} \text{ becomes } \left\{ NiO \;\middle|\; KHO \;\middle|\; FeO \right.$$

But it is better to write the equation in a manner which, though less simple, will be more in accordance with the practical requirements. Thus:

After charge

$$n \,.\, NiO_2 \;\middle|\; \begin{matrix} KHO \\ 12\ H_2O \end{matrix} \;\middle|\; m \,.\, Fe,$$

After discharge

$$\begin{matrix} (n-p)\ NiO_2 \\ p \,.\, NO \end{matrix} \;\middle|\; \begin{matrix} KHO \\ 12 \,.\, KHO \end{matrix} \;\middle|\; \begin{matrix} (m-p)\ Fe \\ p \,.\, FeO. \end{matrix}$$

If I am asked my opinion as to the probability of life, the reply is definite enough. Having had these cells under close observation now for some months, I believe they will live in working order for much longer time than is usual. How much longer I cannot say, but I look forward with some confidence to such a duration as will make the Edison cell a permanent and valuable addition to the resources of electrical engineers.

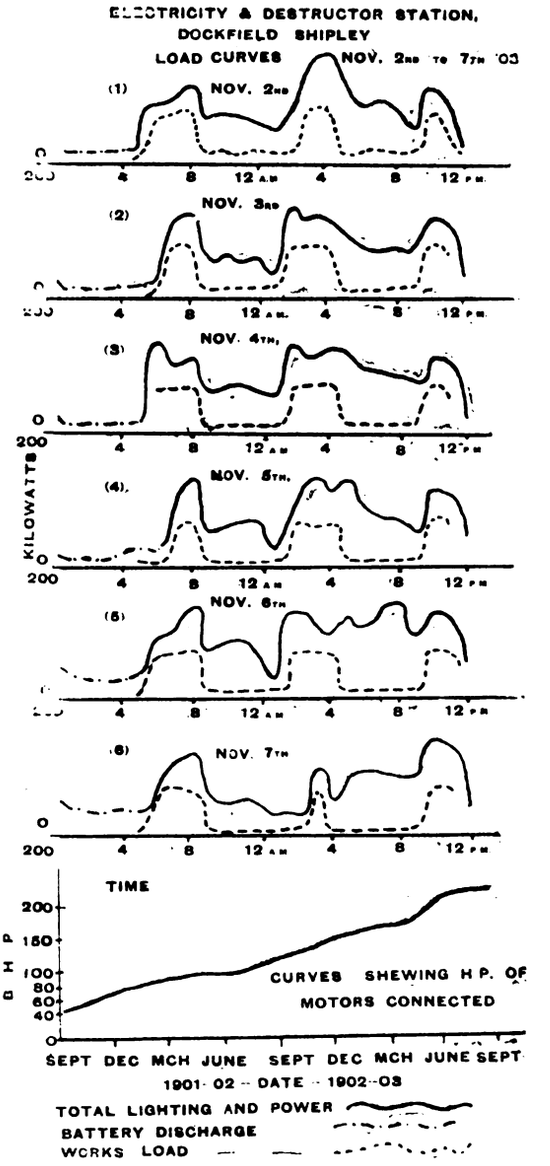
DESTRUCTOR AND ELECTRICITY STATIONS IN SMALL TOWNS.*

BY S. D. SCHOFIELD.

(Concluded from page 809.)

Herewith will be found load curves showing the output for lighting and power at Shipley for the six days ending Nov. 7, 1903, and these have a vastly greater influence on the reduction of costs than any assistance given by the destruction of refuse. Curve No. 7 shows the increase in brake horse-power of motors supplied with current from the same station, quarter by quarter, from September, 1901, to September, 1903 A traction load is no doubt an advantage to a station, but in this case it takes second place to the advantage obtained from a motor load.

The writer considers that whilst economies may be effected in combined stations, it is often at the expense of the electricity undertaking It is a significant fact that the best results are obtained at electricity stations. Obviously the site for a destructor station will be where the cost of carting the bulk of the refuse will be reduced to the lowest figure. The site for an electricity station is in the centre of the area of supply, so that there will be a minimum of expense in laying feeder cables and a minimum loss in supply. If these two coincide, and sufficient land can be acquired to allow for the destructor, clinker yard, mortar-grinding machinery, etc, incidental to a destructor plant, then this is one point in favour of combining the two stations.



With regard to financial arrangements with the Health Committee and the Electricity Committee, the following is a suggested basis worked out on the costs already quoted: The value of 40 units per ton of refuse (less 10 per cent. for cost of keeping coal-fired boiler banked up, ready to take the load when refuse is burnt up, less 10 per cent. for unreliability of supply and varied character of the refuse, less 5 per cent. for management and supervision), at a fuel value of ·266d. per unit, is equal to 8·1d. per ton of refuse. The cost of labour alone in destroying is 1s. 1½d., so that a bonus of, say, 4d. per ton would meet the case. The Health Committee to find interest and sinking fund on the plant, and be credited with any by-products, such as clinker, etc., the Electricity Committee to find all labour, supervision, etc. Repairs to be charged to the Health Committee. This would leave a net cost to the Health Committee for labour of 4d. per ton, which is about equal to the cost for rental of tips. With this payment the destructor would not overburden the electricity supply undertaking, particularly in the early days of the station. Where a sufficient outlet for the power can be found in

* Abstract of paper read before the Leeds Local Section of the Institution of Electrical Engineers.

Digitized by Google

driving mortar mills, sewage pumps, tools, and machinery in a central depôt, then it is preferable to use it in that manner. In adjusting the arrangements, care should be taken that neither side should be making an illegitimate profit at the expense of its partner.

APPENDIX.

The Shipley destructor station was originally coupled to the sewage outfall works, but at a later date it was considered that it would be an advantage to have the electricity works also on the same site in order that the steam raised by the destruction of refuse (over and above that required for sewage pumping) might be used in that department. The result is that sewage pumping and outfall works, refuse destructor, and electricity supply for lighting and tramways are all on the same site. The destructor is of the Meldrum regenerative type, consisting of furnace, combustion chamber, Lancashire boiler, and regenerator. Refuse is tipped into the adjoining hoppers, then withdrawn from the bottom by hand, and fed into the furnace opposite. The cells are so arranged that the fire is continuous over the whole of the grate, the forced draught being localised by closed ashpits. By this method any part of the grate can be worked singly, or any part shut off while the remainder are in use. The air for blast is heated by being passed around cast-iron pipes, through which the gases from the boiler flues are directed. The temperature of the air as it enters the destructor varies from 280deg. F. to 350deg. F., 320deg. F. being the average. One advantage of the open grate is the mingling of the gases from the duller and brighter portions of the fire, thus giving a better and more even combustion in the furnace itself. After passing over the furnace bridge the flames and gases enter the combustion chamber, and the temperature obtained therein is so high that the deposited dust is fused into solid clinker. The maximum capacity of the destructor, with average ashpit refuse, is 50 to 55 tons per 24 hours. At Shipley there is not more than an average daily supply of 25 tons, and this, of course, is easily disposed of. The boiler-house equipment includes a Green's economiser of 192 tubes and two 30ft. by 8ft. Lancashire boilers, with superheaters, these boilers being fired by coal. The generating plant consists of three Parsons turbines direct-coupled to three 240-kw. compound-wound direct-current dynamos, suitable for either traction or lighting; a Tudor battery of 260 cells; a 50-kw. traction motor direct-coupled to two 25-kw. lighting generators, which are used for supplying tramway current from the lighting side, and lighting current from the tramway side, and also running as an ordinary balancer; a reversible battery booster, driven by a motor off the traction 'bus bars, for equalising the load on the traction generators. The sewage pumping plant consists of a 9in. "Gwynne's" centrifugal pump, direct-coupled to a 60-h.p. compound motor, and a 7in. pump coupled to a 30-h.p. compound motor.

DISCUSSION.

Mr. W. Emmott said the author had not placed the destructor in too favourable a light, as evidently if he could do without one he certainly would, but he gathered from the past history of the Shipley station that it was very much indebted to the destructor in its early days. Of course no one would adopt a destructor with the pure object of saving coal. The destruction of refuse in a town was an absolute necessity, and under the circumstances the municipal authority had to get rid of this refuse: then every penny earned by that means was of value, and credit should be given. The difficulty was generally with the Sanitary Committee in that they often wanted the refuse taken and destroyed whilst they were to be charged nothing for the same. Regarding the dust from the destructor, the only way to get over it was to place the electricity station and the destructor back to back. One point about a combined station was that better destruction of the refuse was obtained, because steam was bound to be kept within measurable limits of the standard pressure in order to keep the engines going, especially with a choppy load. If, however, the destructor was simply generating steam for pumping purposes, the steam pressure might be varied 30 per cent., or even 40 per cent., but by so doing there was a risk of the refuse not being so well destroyed as would be the case under a combined electricity and destructor station. He then alluded to the variation in the height of chimneys used in connection with destructor stations, and would like to raise the question as to the average height of the chimney necessary. He maintained that 90ft. to 120ft. was quite enough, but there seemed to be a tendency to carry the chimneys to 150ft., and even higher. He supposed the idea was that the further the chimney was carried the further away the noxious fumes were sent, but, as a matter of fact, there were none. It was said that the firebrick lining of a destructor chimney should go to the top. If there was occasion to turn the gases through the by-pass and regulate this, there was no reason why two-thirds of that lining should not be enough. On a plant with which he was concerned a preliminary test had been made, and he might say that they destroyed 15 tons of refuse in eight hours, the refuse being a combination of sludge which had left the sewage works where the deposit was very rich. The staple trade being woollens, it was noticed that when the sludge was dried down to, say, 60 per cent. of moisture there was a lot of oil, and in order to roughly test the value of this stuff firing-up was done with varying ratios of refuse and sludge. First 2 to 1, then 1 to 1, and, finally, steam was kept up with sludge alone. He saw clearly that there was a great deal in the stoking. The sludge was accumulating at the rate of 60 tons per week, and could not be given away, so that it was necessary to destroy it. Generally, he might say that when the plant was properly working they would be able to get 1·25lb. of steam gross from 1lb. of mixed sludge and refuse in the ratio of 2 to 1.

Mr. W. B. Woodhouse said that he entirely agreed with the author as to the destruction of refuse being purely a sanitary matter, but he was afraid that that was not always believed. Although the question of cartage was important, he thought it was more important to consider the sensibility of the people, and therefore the destructor should be away from the dense portions of the town, and, therefore, hardly the best position for a power station. Barging away to sea was an obsolete method, although there were a great many places favourably situated on Tyneside where the cost of barging the refuse was at the most 5d. per ton, and he did not think any burning could compete with that. Another point was that where coal was cheap refuse was good, and *vice versâ*, and that was where a destructor was useful. Regarding the table given, he noticed that Shipley had a very good load factor, and presumed that the 66·8 included charging battery, etc., and was not the load factor on the running power. He would like some idea as to how many pounds of water per unit generated, and, generally, as to whether the conditions in the various tests were the same; but certainly, with a fair price for coal, 7·1 per unit with a load factor of 66 per cent. was quite absurd. He could generate a unit from 3½lb. to 4lb. of coke, and he was sure that with that load factor he could generate very much more cheaply. The omission of water per unit generated made it difficult to criticise the table, and that rather serious point—namely, the capital cost—was overlooked; also he thought that the lighting and destructor stations should be kept separate, because, if the generating station was put in the centre of the town, where it would feed the area most economically, then that was the wrong position for the destructor, which should be away from the centre of the town. If, however, the destructor was put in the wrong place, then, when the load came on the station, it would be found that the destructor was quite insufficient to deal with the demand, so that actually a combined station was only useful in the early years of an electricity station.

Mr. Pickersgill said that he quite endorsed the previous speaker's remarks. In a short experience he would say this in favour of destructors, that on a low load factor he could generate all the energy necessary for driving nine miles of tramway through one Meldram furnace, although if the load was anything like an average of the maximum he could not do so. There was a great difference of opinion as to the arrangement of destructor boilers, and he had arranged the steam-pipes at Cleckheaton with automatic valves, which were really back-pressure valves, in between the main valve and the steam valve, so that when the steam was highest in the destructor boilers it shut down the check valve on the coal-fired boiler even when the fires had just been blown. As soon as the clinkering process took place the temperature in the combustion chambers fell and thus steam was lost, and as soon as the other boiler got a rush of steam it closed the check valve on the destructor, thus giving time to get the steam up, and thus did not cause the destructor boiler to act as a drag. The refuse that was obtained at Cleckheaton averaged over 70 units per ton destroyed. The figures given by Mr. Schofield were actually taken by watt-meters, and include current for tramway purposes, the load being so arranged on the charging battery on the other generators that the steam was kept practically constant the whole of the time. Had the tramway load been higher, no doubt they could have got more units per ton, as for a considerable time steam was blowing off at the boiler, and the batteries could not take a larger rate of charge.

Mr. A. B. Mountain said that, with respect to the load factor at Shipley, it had probably been taken on the hours that the plant was running and not on the total for the year. He thought that the total cost given—namely, ·26—was too low, as there were few places in England having a lower cost than ·4, and, therefore, the comparison was hardly a fair one. There was a very great discrepancy in published figures as to the actual cost of destroying refuse, and what was really required was some definite figures on capital outlay, interest, special fund charges, and repairs.

Mr. Meldrum said that it would be agreed the author had not put too favourable a construction on the destructor, and he thought he was right, because there was a great danger of people running away with the idea that a destructor was a gold mine. As an instance of the unfavourable comparison in the case of the destructor no superheating was done, and that alone would make a very marked difference, particularly seeing that he had a Parsons turbine which would stand any amount of superheat with distinct advantage. He thought that the 49 units given would have more nearly reached 60 units had superheating been carried out, in which case the balance-sheet would have been more in favour of the destructor. Again, he said that in September he got the best results and that he considered this month one of the best. From a very wide experience, however, he (the speaker) would say that July, August, and September were practically the worst months in the whole year, because during that time very little coal was used in

Digitized by Google

domestic fires, and also that was a period when most vegetable refuse was found. During that period the calorific value of the refuse fell in some places 50 per cent., but on an average it would be from 15 to 25 per cent., and consequently if the author had made a test in November or December under the same conditions he would have obtained very much better results, which, however, were very satisfactory In corroboration of what he had just said, he would mention that tests had been carried on in the London districts for several months past, and during November almost 50 per cent better results were obtained than in September, partly due to the late tremendous rains, and partly due to the fact that more coal and less vegetable matter appeared in the refuse. The author said that the value of refuse was in inverse proportion to the price of coal, but he did not quite agree with him. He had before him tests of a station at which coal cost about 25s. per ton, and the evaporation was 1·41b. of steam per pound of refuse. Again, at Grays, in Essex, where coal was 21s. per ton, the units produced were 42; and at Sheerness, where the price of coal was very high, the evaporation was approaching 1·5 per pound. Again, at Hereford, with coal about 18s. per ton, results had given 1·5 or 1·6 per pound of fuel, whereas the author gave a figure of 1·7 with coal at about 7s. per ton, so that he did not agree with the author's conclusions. In giving the balance-sheet in favour of the Corporation he mentioned £270 clear gain, but did not give the value of the clinker, although he believed that the whole of it was used, and questioned if it were to be bought whether it could be got for less than 2s. 6d. per ton. If this item be added (say, 2,000 tons), there was a further sum of £250 in favour of the destructor, making a total of something like £520 clear gain. To get over the difficulty of putting a destructor in the centre of a town adjacent to the electricity works, some corporations were now putting the destructor at the most convenient point for its purpose whilst putting the electricity works at the most economical point, putting down at the destructor a generator large enough to utilise the whole of the heat, and carrying the current from there on a feeder either to the switchboard of the electricity station or else on to the cables at the nearest point. One place where that was done was near London, and in that case the Electricity Committee received ·75 of 1d. per unit, which was quite a liberal allowance, the whole of the capital charge being placed to the debit of the whole committee. It was rather astonishing to find that, in spite of all that was said against destructors, four out of every five destructors ordered from Meldrums had been in connection with electricity works. With regard to the question of the height of chimneys very much depended upon the locality, but about 80ft. would be found a fair average height, and that met the requirements of any by-laws. With reference to the question of firebrick lining, he thought that two-thirds or even one-half was, as a rule, ample, and in some cases where there were no by-passes there was no necessity to line at all. As regarded barging to sea, it should not be overlooked that it frequently happened, especially in time of storms, that refuse had to lie about the quays, causing a nuisance, and even when it was got to sea a great deal of it was washed back again on to the shore. He knew of cases in New York in which refuse had been taken out 10 miles to sea, and yet large quantities of it had been washed up on the shores.

Mr. Melvin said that a question had been asked about the capital charge and expenditure in various ways, but it was not possible to give reliable figures, the only ones being those which referred to the cost of handling the refuse and turning it from the condition in which it was obtained into harmless products. The cost of labour varied very considerably, but he thought a reasonable figure for men handling refuse and disposing of it would be 9d. per ton. With respect to the question of smell, since the introduction of forced draught destructors had been constructed in which the chimney gases were entirely odourless. He fully agreed as to the height of chimneys mentioned by the previous speaker, and thought that 80ft. or 90ft. were quite sufficient. With respect to the figure of 49·8 units per ton, he was of opinion that if the boiler had been fitted with a superheater this figure would have been increased considerably. On looking up the fuel cost for various towns he found that there were only three places where fuel cost was ·26d., and when it was remembered that the figures obtained at Shipley were being compared with some of the lowest coal-firing stations, he thought it spoke exceedingly well for the destructor. The author did not appear to have included anything for labour in firing the coal-fired boilers, and it appeared that the cost of destroying the refuse would be 1½d. per ton. The cost on that basis, including the labour ·04d., would be ·306d. The cost for coal firing would then be 14·74d., instead of 13·5d., as mentioned, thus leaving a saving in favour of the destructor of 1·24d. The author had not said much as to what the destructor was doing, and the information as to how many kilowatts the destructor was capable of producing, and also if it generated the bulk of the day load, and the coal boilers had to assist it or put on after the refuse was burnt, would be interesting. A 10 per cent. reduction was mentioned for keeping steam up in the second boiler, but it was quite usual to keep a second boiler as a stand-by, and therefore he did not think the 10 per cent. should be put on.

Mr. H. N. Leach (communicated) gave particulars of a test which Mr. Hammond had carried out on plant erected by Messrs. Heenan and Froude at Gloucester. The furnaces consist of two grates, the boiler being a cross type of Babcock and Wilcox's, mounted over the furnaces with a separate combustion chamber intervening. The grate area is about 66 square feet, and the rate of burning throughout the test was about 50lb. per square foot per hour, making a total of about 1¼ tons of refuse consumed per hour. The actual evaporation was 1·76lb., the feed being at a temperature of 55deg. F., and for the first six hours of the test the load was an artificial one, giving an average of 140 kw. On two occasions the load fell to 100 kw., half an hour being the period of the fall and rise. Steam blew nine times for continued periods during the first six hours of the test, the forced draught being cut off during such periods, whilst during a subsequent six hours the destructor carried about 50 kw. on the tank, the street-lighting of the city amounting to about 40 kw. He thought that these figures constituted a record performance, more especially for the South of England.

Mr. Frank Broadbent (communicated) stated that the conclusion arrived at in the paper bore out his own views, and, except in special cases, he could see no advantage to the electrical side from the combination of the two. There were considerable advantages to the sanitary side of the undertaking, not the least of which was the higher economy and efficiency of the destructor, due to its being under the control of an electrical engineer whose training ensured that nothing was lost.

Mr. Schofield, in reply, said that most of the questions had been replied to by other speakers. With regard to the question of barging refuse to sea, he quite agreed that it was an obsolete method. The capital cost had been overlooked in the paper, as he was only anxious to find out the fuel value of the refuse. With regard to the load factor, one set was running on tramway load the whole day and another set on lighting, and it would be seen from the paper that the load factors were given separately for the two outputs, whilst, in addition, no sets were running at full load. The load factor was taken on a basis of 20 hours a day, which was approximately the number of hours current was required for the cars. With regard to capital outlay, if a destructor plant was put down for destroying refuse alone, it would not be so great as in the case of a combined station, because no very expensive boiler or economiser would be necessary, and, therefore, the figures varied enormously. What was meant by the statement that the value of the refuse varied according to the price of fuel, was that the price of household coal, as a rule, would determine the fuel value of refuse. If household coal was obtained at 10s. to 15s. a ton it was not so carefully burnt as was the more expensive coal, and consequently the fuel value of ashpit refuse was higher in the first case than in the last. With regard to the value of clinker, that did not concern the electricity department, nor was it an essential factor in the consideration of the two stations, as it was purely a sanitary matter. As a matter of fact, the clinker at Shipley was used for bacteria beds, and before the destructor was started thousands of tons were carted at a cost of 10d. per ton, so that the figures divided by 3 would give the results at Shipley if all the clinker was valued at 10d. per ton. It had been said that the cost of coal—namely, ·266—was very low, but it would be noticed that he had not taken the units sold, but generated, the figures taken from that and other sources giving the cost of coal. With the load at Shipley ·266 was not a very low figure, and he was inclined to think that it might be reduced. It should always be borne in mind that the steam-raising plant must be capable of taking the whole load of the station, as, after heavy rains, the refuse was saturated with moisture, and in winter the fall of snow would prevent the collection of refuse for probably three or four days.

HOT-WATER HEATING FROM ELECTRIC STATIONS.

Heating from central stations constitutes a topic which is of ever increasing importance to the central-station engineer. There are several systems which may be employed, falling into the broad divisions of steam and hot water. If the latter be chosen, the one-pipe or two-pipe method of distribution may be used. In a recent issue of the *Western Electrician* Mr. Alton D. Adams discusses these two systems of hot-water heating at some length and shows their relative advantages and disadvantages. Two interesting examples of hot-water heating are quoted by the author in order to illustrate some of the differences between the one-pipe and the two-pipe system—*i.e.*, the Toledo Heating and Lighting Company at Toledo, Ohio, and the Miami Light, Heat, and Power Company at Piqua, Ohio. The Toledo plant is on the double-pipe system, and in 1900 had 16,776ft. of double mains, covering probably that length of street, and containing 33,552ft. of single pipe. In the single-pipe system at Piqua the total length of pipes in street mains is about 9,650ft., and these pipes cover practically an equal length of streets. At Toledo the most distant part of the mains is about 0·75 mile from the station, and at Piqua the corresponding distance is 0·7 mile. The Toledo system had been in operation about five years up to 1900, and then had radiating surface to the amount of 175,000 square feet connected in 199 buildings. In the Piqua system, with less than 0·3 of the length in main pipes at Toledo, the capacity is 115,000 square feet of radiating surface, and 120 service connections are provided. The Toledo system lighted 450 houses and heated 199 buildings during the six months ended Jan. 1, 1900, with the following satisfactory results: income from lighting, £1,813; income from heating, £1,980—total income, £3,793; fuel expenses, £1,008; salaries and wages, £565; all other expenses, £379—total expenditure, £1,952; leaving a handsome balance of £1,841.

NOTES.

Surface Contact for Railways.—Mr. L. W. Pullen's surface-contact system of electric traction as applied to railways was put on trial last week in America on a mile of experimental track on the Pennsylvania Railroad. Report states that a speed of 85 miles an hour was attained, and that in other respects the results were successful.

Cable Transmission Record.—The all-British cable has accomplished another record in the transmission of news from Australia to Great Britain, the close of the Australian innings in the test match this week having been sent by the Pacific-Anglo in the time of 3½ minutes from the Sydney cricket ground. Considering the number of retransmissions that take place, this is a highly creditable performance.

Telegraphic Charges to France.—A strong committee of French Deputies has been formed to carry out a proposal for reducing the telegraphic rates between England and France. As the telegraph rates are now ½d. per word throughout each country (London to Ireland, or Paris to Algeria and Tunis), 1d. per word in place of the present rate of 2d. per word is advocated between Great Britain and Ireland and France.

The Electro-Harmonic Society.—To-night this society will hold the third concert of its present season in the King's Hall of the Holborn Restaurant, Mr. A. P. Trotter being in the chair. Mr. Dalton Baker and Mr. Whitworth Mitton are the vocalists, and, as usual, Mr. Alfred E. Izard will be found at the pianoforte. Mr. T. E. Gatehouse is down for a couple of violin solos, and an orchestra will play selections. There are also some humorous turns, which altogether make a very attractive programme.

"African World" Annual.—For their first Christmas number the proprietors of the *African World* have brought out an exceptionally attractive issue. Its excellent get up leaves nothing to be desired, and the contributors to its columns include such writers as Sir Harry Johnston, Mr. W. T. Stead, Mr. F. C. Selous, Dr. Carl Peters, and Prof. Ronald Rons. The mining section of the annual has been compiled on somewhat original lines, and is as up-to-date and comprehensive as possible. The complete issue runs into some 170 pages.

Automatic Lubrication.—Before the Dundee Institute of Electrical Engineers, Mr. David Scott read a paper last week in which he described several devices for the automatic lubrication of electrical machinery. He emphasised the importance of the subject by speaking of the losses caused by bad lubrication, and stated that with good automatic lubrication wear and tear could be reduced to a minimum. He was not an advocate of high-priced oils as lubricants. If the bearing surfaces had been made ample, ordinary mineral oils of 907 specific gravity were quite good enough; and for cylinders and valve faces, unless very highly superheated steam were used, ordinary cylinder oil did very well. Mr. Scott concluded by enumerating and describing the various lubricating devices on the market, and offered some good advice drawn largely from personal experience.

New Books.—"The Electro-Chemist and Metallurgist" (Sherard Cowper-Coles and Co., Limited, Westminster); 2s. This publication—the organ of the Faraday Society—contains one or two interesting papers, among which we notice the following: "Some Notes on the Welding of Aluminium," by Mr. S. Cowper-Coles; "Practical Notes on the Electro-Depositing of Copper on Iron, Carbon, and Zinc," by Mr. S. Cowper-Coles; and an article describing the impingement processes in the rapid electro-deposition of copper.—"L'Electricité dans les Mines en Europe," by Emile Guarini (Ramlot Frères et Sœurs, 25, Rue Grétry, Brussels); 5fr.—"The Miller Signalling System" (The British Miller Signal Syndicate). This is a technical description of the system, with detail drawings, and is of considerable interest. It will be remembered that the system was fully described in a recent issue of this journal.

Wireless Telegraphy.—The other day an illustration of the practical value of wireless telegraphy at sea was afforded by the case of the steamer "Kroonland," which was partially disabled when 1,730 miles west of the Fastnet. The wireless telegraph apparatus with which the ship is equipped was immediately brought into use, and the captain opened up communication with the Marconi station at Crookhaven, whence messages were sent to the agents of the boat. In this way the captain received his instructions, and the "Kroonland" put back into Queenstown. Many of the passengers on board also sent messages to their friends on shore, and in some cases were received not only from England but from the Continent before the Fastnet was sighted. It is announced that the German Wireless Telegraph Company is endeavouring to establish communication between Berlin and the Swedish coast near Stockholm, a distance of 650 miles.

Electrical Machinery in Russia.—As we have pointed out in these columns quite recently, a great part of the electrical machinery and plant being used in Russia was imported mostly from Germany and Switzerland, and some from England and America. It seems likely, however, that a restriction will sooner or later be imposed on the electrical imports, in order, if possible, to increase the consumption of home products. The matter has been taken up by an organisation of some 14 of the leading electrical manufacturing establishments, and a petition has been addressed to the Minister of the Interior and to the Minister of Finances at St. Petersburg, in which the Government is asked to require the Municipalities of St. Petersburg and Moscow to buy all their electrical machinery and apparatus in the country. This is the thin edge of the wedge, and the manufacturers hope that other municipalities who may be carrying out electrical schemes will be obliged to cease importing from foreign houses, and to purchase only in the home market. Should the policy indicated meet with the approval of the Russian Government, the German, Swiss, English, and American houses will all be affected in a greater or lesser degree, although the biggest loss will fall on Germany, which at present supplies most of the electrical plant imported into Russia.

Electrically-Driven Looms.—It is gratifying that in the struggle going on between factories and domestic industries in some parts of Germany, the latter should occasionally have its share in the achievements of modern engineering. A co-operative enterprise with a view to supplying the domestic weavers (of the silk ribbon trade) in the Southern Black Forest with electric power has lately been started in the Hotzenwald district, it being contemplated to drive by electricity the looms of 500 weavers living in 28 different localities. The first cost of the whole of the power plant is estimated at about £17,000, this sum to be supplied by the Wald-Elektra Säckingen-Waldshut Power Company, apart from a grant by the Government. The significance of this enterprise is its enabling the above branch of textile industry to be preserved as a house industry, securing a yearly income of about £15,000 to the poor inhabitants of that part of the forest. Moreover, the diminution of strain on the physical strength and health of

Digitized by Google

the weavers will allow of people of even moderate strength devoting themselves to domestic weaving without endangering their health, so that a rational division of work can be made between the members of the same family, especially during the season of rush in the silk trade. Moreover, weavers will be in a position to deal with stouter goods, securing them higher profits, apart from the sanitary advantages attendant on electrical operation and lighting.

"The Electric Museum."—The third number of this paper, which is edited and published by Mr. A W. Hill at Colombo, has just reached us. The interesting matter given in this issue covers quite as wide a range as that in the preceding numbers, and is remarkable for the personal comments of the editor. Scorning the editorial "we," Mr. Hill writes in the first person, and gives his opinion and advice on subjects ranging from lynching to the scaring of locusts by electric sirens. The Russian electric notes give a very poor account of the electrical industry in that country. The following extracts from the editorial note columns will interest our readers, and show the general type of the information given by the only electrical journal in the East: "In view of the somewhat frequent fires in coal sheds in Colombo due to spontaneous combustion, I would suggest that a thermostat, or mercurial thermometer, be fixed inside sheds, provided with electric alarm contacts which would cause the electric bell to ring, thus indicating a possible outbreak of a serious fire on the premises." "I find that some native storekeepers in Colombo—usually Sinhalese and Tamils—may be regarded as disciples of the electric science. It is true that they have not the remotest idea as to what volts, amperes, and ohms really signify; but they know to a nicety how to prepare electro-plating solutions for nickel-silver-gold plating spoons, forks, rings, candle-holders, etc. Smee's primary cells are usually used. Most of these electricians cannot talk English; but, fortified with a rather ancient electric battery, they make, I guess, good profits out of this particular application of electricity."

A Protected Third Rail.—The idea of a protected third rail in electric railway operation has only lately been put to practical use in the States, and it is believed to be the first instance of the kind. Mr. J. E. Wallace, in the course of a long article in the *Street Railway Review* describing the Wilkesbarre and Hazelton Railway, refers to it as a novelty. Of course, the objects of a protected conductor rail are twofold—first, to prevent the formation of ice on the rail; and secondly, to prevent personal injury by accidental contact with the rail. The protection consists of a 2in. by 6in. pine plank held directly over the rail at a distance of 2½in. This pine plank is supported every 8ft. by 3in. by 4in. oak posts, cut out to clear the side motion of the shoe when journals and track become worn. In places which are not subject to severe snow and sleet storms the usefulness of this protection may perhaps be questioned, but in the test runs described in the article, where part of the third rail was exposed and part protected, the difficulty of running a car along the exposed portion after a sleet storm was in marked contrast with the ease and smoothness with which it ran after reaching the protected part. Another arrangement for keeping the third rail clear of ice has been devised by Mr. F. Hedley, the chief superintendent of the Interborough Rapid Transit Company of Chicago. It consists of scrapers which can be lowered on to the contact rail in front of the collecting gear. The actual scrapers are made of thin plates of steel cast into a block, which is suspended from the car truck, and which can be raised and lowered at will by the motorman. The individual plates are placed at an angle across the rail so that they are oblique to the same, and hence able to ride over the joints without trouble. The inclination of the plates also serves to clear off the ice as it is straight from the rail surface. It is proposed to add one of these scraping devices in front of each of the contacts. The system is to be tried extensively this winter.

Oxidising Action of Radium Rays.—Mr. Wm. B. Hardy and Miss E. G. Willcock have been jointly studying the oxidising action of the rays from radium bromide as shown by the decomposition of iodoform. Their conclusions have now been published, and are abstracted in the current issue of the Chemical Society's *Journal*. A solution of iodoform in chloroform rapidly becomes violet on account of the decomposition of the iodoform with liberation of free iodine. The decomposition only takes place if oxygen is present, but the amount necessary is exceedingly minute, and is induced by a radiant energy. The decomposition is accelerated by the presence of sodium chloride, potassium chloride, potassium nitrate, lead nitrate, barium nitrate, and barium chloride, but is retarded by potassium sulphate, calcium carbonate, barium sulphate, and magnesium carbonate; the influence of these salts seems to be a surface action entirely. The influence of the radiations from radium bromide in promoting the decomposition has been studied. By suitably screening the tube containing the radium salt, it was found that the β rays are mainly effective in causing the decomposition, but the γ rays are also endowed with chemical activity. The Röntgen rays also cause the change to take place. The authors conclude that the physiological action of radium rays is due to their power of penetration rather than to the fact that they exert any novel or very intense chemical action. They reach parts which are shielded by a cuticle very impervious to light waves, and in the subjacent tissues they induce some process of oxidation which does not take place without radiant energy.

Architects and Electrical Contractors.—Before the Leeds and Yorkshire Architectural Society recently Mr. Edwin C. Wallis gave a lecture on electrical work as affecting architects. He observed that electric hoists were coming more and more into use, working either with continuous-current, single-phase, or two-phase current. They were in some respects superior to the hydraulic hoists, and the cost of operating the electric hoist was less when a cheap supply of energy was available. Remarking on the progress of the electric light in the last few years, the lecturer pointed out that Leeds began with a plant of 500 h.p., which had now been increased to 14,000 h.p., with 4,000 h.p. more in view. In no department of civil life had greater advances been made than in electrical work and its accessories, and still the advance went on. He took the opportunity of expressing an opinion as to the attitude of architects towards electrical contractors. To the contractor worth his salt no one had been a better friend than the architect, and the profession had welcomed gladly every worthy service that the electrician had been able to render. Architects had found time to make the setting of the light worthy of its surroundings at a time when the electrician had but one idea, such as used to be termed "a bottle on a string." Men of education and taste devoted time and attention to enhancement, and referring incidentally to the electric lighting of the Rylands Library at Manchester and St. Paul's Cathedral, he mentioned as a contrast the present art gallery and reading-rooms connected with it at Bradford. He said it should not be in the power of any man or any committee to make hideous public rooms, whose influence should rather be to gladden and refine the thoughts of men who resorted there. If the profession did no other public service, it at any rate strove to protect the world from constructive vandalism and furnished ideals for the men and women that were to be.

Gloucester Electrical Undertaking.—Mr. W. J. Bache, the city electrical engineer of Gloucester, gave a lecture at the Municipal Schools last week on the provision of generating plant for the city tramways. These lines, it should be stated, are not yet electrified, although the Corporation bought them from the company for £26,000 in 1901 with that object. The work of converting the system to electrical working, however, was recently commenced, and is going on encouragingly, and Mr. Bache, in his lecture, showed what steps had been taken to provide a sufficient supply of electric energy for the trams when they start running. It seems that a service of 20 cars was originally decided upon, and to deal with these Mr. Bache explained that about 250 kw. of plant are required. The lighting plant at present installed at the electricity works consists of two 300-kw. sets and one 150-kw. set. One of the former sets is installed as a stand-by, and in deciding on the arrangements to be made for a traction supply, the Electricity Committee considered the possibility of utilising at least some portion of the lighting plant. The number of connections to the lighting mains at present is equivalent to 26,000 8-c.p. lamps, and less than half—some 10,000 or 11,000 lamps—are burning at the one time. As a matter of fact, the two working sets at the works are capable of furnishing current for 15,000 lamps, so that there is still a useful margin before the plant is fully loaded. True, that margin is being continually encroached upon by the increasing demand for the electric light, and in a short time it will probably be necessary to extend the lighting plant. For the present two 200-kw. traction sets are to be installed, one of which will act as a stand-by, and both be suitable for working either a traction or lighting load. Although the original intention was to give a seven-minute service with 20 cars, another 10 cars have since been ordered, but it is estimated that the provision of plant at the generating station will be ample for the present to meet the increased demand. At the conclusion of his paper Mr. Bache was accorded a hearty vote of thanks.

Stationary Electric Waves.—A meeting of the Dublin Local Section of the Institution was held on the 10th inst. at the University College, Dublin, when a most interesting lecture, illustrated by experiments, was delivered by the Very Rev. Monsignor Molloy on "An Experimental Study of Stationary Electric Waves," with special reference to the phenomena of electric resonance and overtones. The lecturer pointed out the close analogy between the resonance of an electric circuit and the resonance of an organ pipe The apparatus consisted of a pair of Leyden jars, which could be joined in series or paralled as desired, and an adjustable self-induction, by means of which the period of an oscillating discharge between two zinc balls could be varied at will. The jars were charged by means of a powerful induction coil. The resonating electric circuit consisted of a wire wound round a vertical rod one end of the wire, terminating in a ball mounted on top of the rod, the other end being attached to the inner coating of one of the Leyden jars. When the period of the oscillating discharge was made the same as the natural period of the wire, brush discharges and sparks issued from the knob attached to the free end of the wire and vacuum tubes held near it were lit up. The possibility of operating two different wireless telegraph circuits simultaneously and independently by means of resonance was very prettily shown by using pairs of circuits of the same period as sender and receiver, each pair being tuned to a different pitch. The signals were made visible by means of a vacuum tube placed near the free ends of the receiving wires. In order to show overtones a long rod some 10ft. in height was over-wound with a considerable length of wire. The oscillating circuit attached to the lower point of this wire was then adjusted to give first the fundamental and then the harmonics of the wire, the electrical oscillations being made visible by the brush discharges between the rod and a fine vertical wire connected to earth and stretched parallel to the rod at a distance of about 2in.; also by moving a vacuum tube up and down beside the column. A hearty vote of thanks was passed to Monsignor Molloy at the close of the lecture.

St. Marylebone Electric Light.—By the decision of the High Court in last Friday's proceedings, which will be found reported elsewhere in this issue, the Borough Council of St. Marylebone have to find a sum of £60,000 to pay to the Metropolitan Electric Supply Company in connection with the extension of so much of its business as is within the St. Marylebone area. This is the condition on which the Court has allowed an extension of time for completing the purchase until Feb. 29, and the Council would have to levy a 9d. rate in order to raise this preliminary amount. What the Council propose to do is, of course, to promote a Bill in the ensuing parliamentary session to constitute themselves an electric lighting authority, which would remove the difficulties in the way of borrowing the whole of the purchase money; but they must obtain the consent of the ratepayers before this can be done, and the ratepayers, generally speaking, are not in favour of the scheme. At the Council meeting on Thursday last week a most influential deputation waited upon the Council, strongly urging them to endeavour to come to an understanding with the electric light company to relieve the borough from the present arrangement, and complaining that before entering into any undertaking of the sort the Council ought to have consulted the ratepayers. In spite of this, the Council affixed their seal to the petition to Parliament, but at the same time agreed to the appointment of a committee "to confer with the Metropolitan Electric Supply Company, and to report to the Council the terms and conditions on which it will agree to set aside the award." If the negotiations with the company should come to nothing, the Bill will have to be proceeded with, and in that case Mr. Justice Buckley has said he would be willing to further extend the time for the completion of the purchase. We understand that the preliminary payment of £60,000 has to be handed over to the company before Jan. 31 next. The Council, at a special meeting held yesterday, were advised by their Finance Committee that it would be better to borrow the sum from their bankers and to leave the question of the extra rate until the usual time for fixing the amount of the next half-year's rates.

Treatment of Slimes by Electrical Precipitation.—In a paper read by Mr. F. T. Mumford before the Australasian Institute of Mining Engineers, and reprinted in the *Transactions* of the society, there is an interesting discussion of the treatment of slimes by cyaniding and electrical precipitation on mercury. The Riecken process, which employs this method, has been in use at the South Kalgurli gold mine since the end of 1900, and about 3,000 tons per month are treated. The advantages claimed for electrolytic precipitation of gold on mercury are numerous. First, extraction and precipitation may be effected without filtration, and the solution need not be clear for precipitation. The precipitation is equally good whether from strong or very weak cyanide solutions, and the presence of copper salts is not detrimental. The gold is recovered as an amalgam, which only requires retorting and melting. Amalgamation of slimes before is unnecessary, as any coarse gold present is amalgamated during precipitation. The essential features of the mercury cathode is that the

Digitized by Google

surface of the mercury should be as large as possible and be kept in perfect condition by some simple means; the minimum quantity of mercury should be used, and the right current density employed. Mumford's electro-cylinder consists of a steel-plate cylinder lined with amalgamated copper, and with wooden ends. It is supported on rollers and rotated at five revolutions per minute. The anodes are 2in. round iron bars, supported from end to end of the cylinder, and making electrical contact by means of brushes outside the cylinder at one end. In use, mercury is poured in until it is ½in. deep on the bottom and the cylinder is filled with charge to within a few inches of the top. The current density to be employed depends largely upon the condition of the surface of the mercury. When the cylinder is maintained in rotation, a current density of 0·8 ampere per square foot can be used as a maximum, but any higher density leads to a partial surface deposit of gold which does not amalgamate, and which is mechanically retained in the pulp. At two amperes per square foot it is found that none of the deposited gold amalgamates, and all is lost. With weak solutions the weight of gold deposited is not in proportion to the current density, and a current density of 0·5 ampere is practically as good as one of 0·8 ampere per square foot. Generally speaking, the potential difference may be from three to five volts.

New Type of Transformer.—An article recently appeared in the *Elektrotechnische Zeitschrift* describing a new type of transformer, of which Mr. E. Ziehl is the inventor. The construction adopted in this case differs from the usual arrangement, which is to have the three cores of a three-phase transformer on one plane, or at the angles of an equilateral triangle, with two yoke pieces in common to all three. The new arrangement consists in the superposition of two or more cores, each forming a closed magnetic circuit. The author states that this construction has the advantage of considerably simplifying the manufacture, inasmuch as for single, two, and three phase transformers, equal cross-sections for the iron sheets, equal patterns for the magnet coil, and equal armature parts can be used. Comparing three individual transformers with a three-pole transformer of the new construction, the latter shows under otherwise equal conditions a considerably reduced weight of iron, inasmuch as the number of iron yoke pieces is only six instead of eight. With the same magnetisation the losses are, therefore, diminished. Also, when the heat radiation of the new type is compared with that of the three-core type it is found that the former has a considerably larger cooling surface, and a considerably greater capacity to dissipate the heat. The difference between the maximum inner and outer temperature of the iron will be about one-quarter of that in the old construction, which means that the maximum induction in the new type can be chosen higher. The case is similar with the coils, and another advantage in this connection is the division of the copper coils into as many parts as possible, thus getting a large cooling surface. From the possibility of a higher magnetism of the iron and a larger cooling surface there results naturally the possibility of a higher current density in the copper, and, therefore, saving in copper and iron. An influence of the magnetic fluxes upon each other cannot take place, as the middle yoke pieces between two phases bring about an equalisation of a one-sided load, because an excess of lines of force of one phase cannot enter into another phase winding, but has to travel through the intervening yoke piece. The loss of potential from no load to full load caused by the leakage and the ohmic loss has with equal load on the phases the same percentage value in each of them, because, apart from the ohmic loss, the lines of leakage, or the leakage potentials, which appear on short-circuit of the transformer are equal in each phase. A transformer of 25 kw. capacity, running at 2,200/210 volts and 50 cycles, has a total weight of about 776lb., including the oil, of which weight 113lb. were for copper and 256lb. for the iron sheets.

Nickel Nitrate.—In the last number of the *Physical Review* Mr. Wm. McClellan gives the results of a research he has made in the Randal Morgan laboratory at the University of Pennsylvania into the thermo-electric behaviour of nickel nitrate, thus continuing the earlier work on the subject of Walker, Faraday, Gore, Ebeling, Hagenbach, and Bouty. In the arrangement of the apparatus the solution, made with Kahlbach chemicals in pure distilled water free from ammonia, was contained in small beakers, about 3cm. deep and 3cm. in diameter, connected by a tube of 15cm. bore. The electrodes were of platinum wire, the ends being connected to copper wires which went to the potentiometer. Measurements of E.M.F. were made with a Leeds potentiometer, which was calibrated by means of a Weston cadmium standard cell, with practically zero temperature correction. From the final curves plotted from the experiments, it is reasonably certain that the thermo-electric power of the electrolyte used was nearly zero. There was some trouble in the measurements, but this is explained by the extreme sensitiveness of the cell to polarisation. This accounts for the presence of positive and negative curves, although the greatest care was taken in the observations. It was found absolutely necessary to have the electrodes in a definite condition at the start. In order that the potential difference should be constant at constant temperature, the author says it is absolutely necessary that the electrodes should be subjected to a prolonged bath in strong nitric acid. The effect of vibration of the electrodes was not entirely settled by the experiments. It is true, however, that in a solution which contains air, the vibration has a steady effect if the vibration does not stir more air into the solution. If any good is to be obtained, the electrodes must be arranged with nodes at the surface of the electrolyte. A number of interesting effects might be obtained if a cell were designed in which the vibrations could take place without vibrating the surface, or if the part vibrating at the surface were insulated so that it did not form part of the electrode proper. The experimenter found that the presence of air in the solution caused great irregularity. Therefore boiling the solution free from air had a marked effect on the potential difference. Here the removal of the air showed the masking effect of the polarisation much more easily. If the thermoelectric power amounts to anything, it is probably positive—that is, it flows from cold to hot externally. In this connection it may be mentioned that the curves of sulphates and chlorides as shown by Hagenbach in 1894 show changes in potential difference of from 0·01 to 0·15 volt for a temperature rise of 60deg. C., whereas the author found that in the case of nickel nitrate the effect would not be over 0·001 volt, even with polarisation effects added on or subtracted, as the case might be. It is purposed to go on with this work until, if possible, an exact value is obtained for this effect, whether zero or otherwise.

Electrical Progress in Italy.—In its industrial development, Italy as a country has suffered largely from having no coal supply of her own, and consequently having to import her fuel from foreign countries. The trend of electrical progress in Northern Italy especially is, however, rendering that country every day more independent of foreign supplies of coal, and its effects have been particularly noticeable in one of the principal coal-mining districts of England—viz., in Durham and Northumberland. The exports of coal from Newcastle-on-Tyne to Italy have been falling off

Digitized by Google

very considerably in the last few years, and this to a large extent is undoubtedly due to the development of water power by the Italians, particularly in connection with the more extended use of electricity as a motive power. This is strikingly illustrated in a report which has been prepared by the Chevalier V. A. Montaldi, the Italian vice-consul at Newcastle. Up to a very few years ago the distribution of electric energy in Italy was solely confined to illuminating purposes, that devoted to motive power was insignificant. Since then, however, the transmission of electric power over long distances has been accomplished, and no later than three years ago there was in North Italy over 65,000 h p. of hydraulic force being converted into electrical energy—*i.e.*, 16,000 h.p. in Piedmont, 35,000 h.p. in Lombardy, and 12,000 h.p. in the province of Venice. At the end of last year it is calculated that 37,000 h.p. was used in Piedmont, 45,000 h p in Lombardy, and 22,000 h.p. in Venice, a total of 104,000 h.p., whilst machinery was under construction to produce a further 1,006,000 h.p. in the same districts. Lombardy especially gave a great example to the various countries to run their industries nearly independent of coal. Engineers are familiar with the large electric works at Vizzola, on the River Tessin, developing 20,000 hydraulic horse-power. They are the biggest electric works for the transmission of electric power that exist in Europe, and further enormous additions are to be added in order to increase the output to 25,000 h.p. The energy is distributed in the Milan district alone, and represents a diminished coal consumption valued at about £80,000 sterling. In Italy all waters belong to the Government, and from official statistics published in 1899 the minimum hydraulic force during summer is estimated at about 2,654,000 h.p., and by constructing some small canals this power could be increased to 4,600,000 h.p. In the electrification of steam railways it is known that the Italians have been particularly active, and the results have been significant. In one striking instance—*i.e.*, the electric lines from Milan to Varese, which is about 47 miles long—the receipts have more than doubled under electric traction, and the profits of the line in 1902 were half as much again as in 1897, when steam power was used. The lines now worked by electric energy in Lombardy alone are the Milan and Varese Railway, 47 miles long; the Lecco, Colico, and Sondrio Railway, 67 miles in length; and the Milan and Mauza Railway, 7½ miles long—making a total mileage of about 121½. The lines which are about to be electrified have a total mileage of about 445—*i.e.*, 385 in South Italy and 60 in North Italy. The prices per horse-power of electric current generated by hydraulic power vary according to the distance from the generating station to the place of consumption. In the districts where water power exists the cost is about £2 per horse-power per annum, increasing up to as high as £5 per annum, according to the distance from the generating plant.

An Electromagnetic Theory of the Aurora Borealis.—In a paper previously read before the French Academy of Sciences, Mr. C. H. Nordmann had shown theoretically that the sun must emit Hertzian waves, the intensity of which is a maximum in the regions and at times of greatest solar activity. From this proposition an explanation of the solar corona and its peculiarities, as well as of the spectra of comets, was derived. Now, in a recent note presented to the Academy the author tries to show that the same explanation would elucidate the nature of the aurora borealis, as well as the origin of the oscillations and disturbance of terrestrial magnetism. Previous investigations have shown a close connection to exist between the spectrum of the aurora borealis and that of the light surrounding the cathode of a tube containing oxygen and nitrogen. It is hence inferred that the aurora borealis is a cathodical phenomenon occurring in the upper exhausted atmosphere. Some special properties of the aurora borealis are explained by the well-known property of cathode rays to range themselves along the lines of force of a magnetic field. As regards the only difficulty left by the explanation—viz., the origin of the cathodic phenomena giving rise to the aurora borealis—the author solves this question by means of the following proposition. Tubes containing sufficiently exhausted gases will, as shown by Ebert and Wiedemann's work, become illuminated under the influence of Hertzian waves, the luminous phenomena thus produced being identical with the cathode phenomena of Geissler tubes. The author, therefore, thinks auroræ boreales to be caused by cathodical phenomena produced in the atmosphere under the action of the Hertzian waves emanating from the sun, according to the well-known property of these waves. On this explanation the different periods of the auroræ boreales will easily be accounted for. The fact that the greatest frequency of the auroræ coincides with the greatest frequency of sun spots is due to the greater intensity exhibited by the Hertzian waves given off from the sun during the maximum of sun spots. The period of the auroræ seems to correspond with the period of rotation of the sun. This is accounted for by the fact that the regions of maximum activity of the sun performing a complete rotation in about 26 days, the aurora borealis must of necessity possess an identical period. The diurnal period of the phenomena is equally explained by this theory, though the maximum production should correspond with the maximum of solar radiation in a given point—*i.e.*, the passage of the sun through the meridian—the apparent maximum of the auroræ cannot be observed until in the early hours of the evening, in accordance with experimental facts, as the brilliancy of daylight at the instance of the real maximum will hide the phenomenon. The oscillations of the magnetic needle, as is well known, exhibit a period closely corresponding to the period of sun spots, like that of aurora borealis It thus seems as though the variations of terrestrial magnetism should be due to the same cause as auroræ boreales. On the other hand, it is generally presumed that the intensity of terrestrial magnetism and the variations of this intensity are in close connection with the general electric currents in the atmosphere, produced mainly in the upper exhausted layers of atmosphere, being relatively conductive, under the influence of the unipolar induction of vaporisation. Prof. Righi has finally shown the conductivity of an exhausted gas tube to be notably augmented under the influence of Hertzian waves, the tube thus behaving like a coherer. Now, the theory of the author will readily account for the period in terrestsial magnetism. At the time of the maximum of the spots the more intense Hertzian waves of the sun will give rise to a relatively large diminution in the resistance of the upper atmosphere, resulting in an increase in the intensity of the electric currents in the atmosphere, and accordingly in an increase in the intensity of terrestrial magnetism. The occasional sudden production of auroræ boreales, as well as the variations in the intensity of terrestrial magnetism, may equally be explained on the theory of the author. Many examples are known of magnetic thunderstorms attended by auroræ boreales and coinciding with a violent disturbance of a solar spot, as detected by means of the spectroscope. The best instance for the truth of this theory is, however, derived from the fact observed by Young as far back as 1883, that any considerable disturbance of the solar surface will be transmitted to our terrestrial magnetism with the speed of light. Now, this is just the velocity of Hertzian waves.

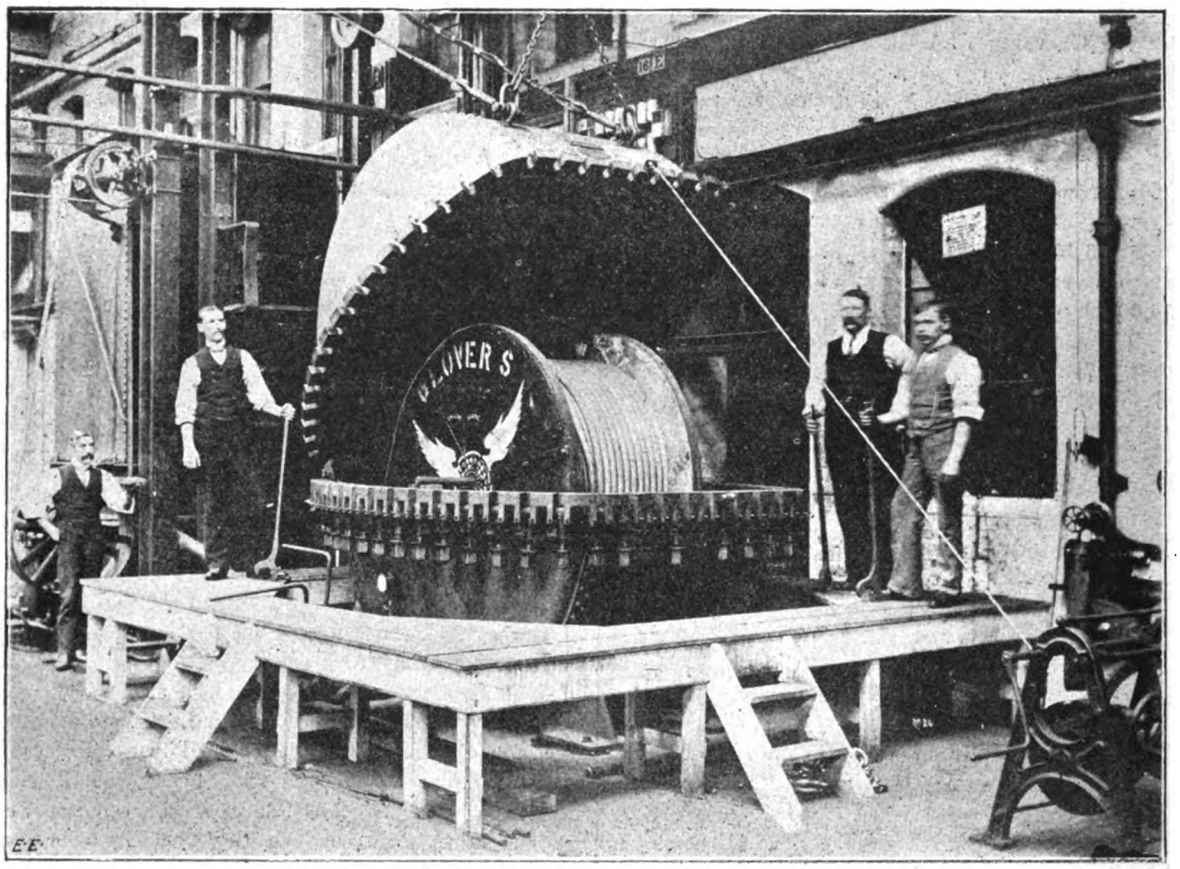
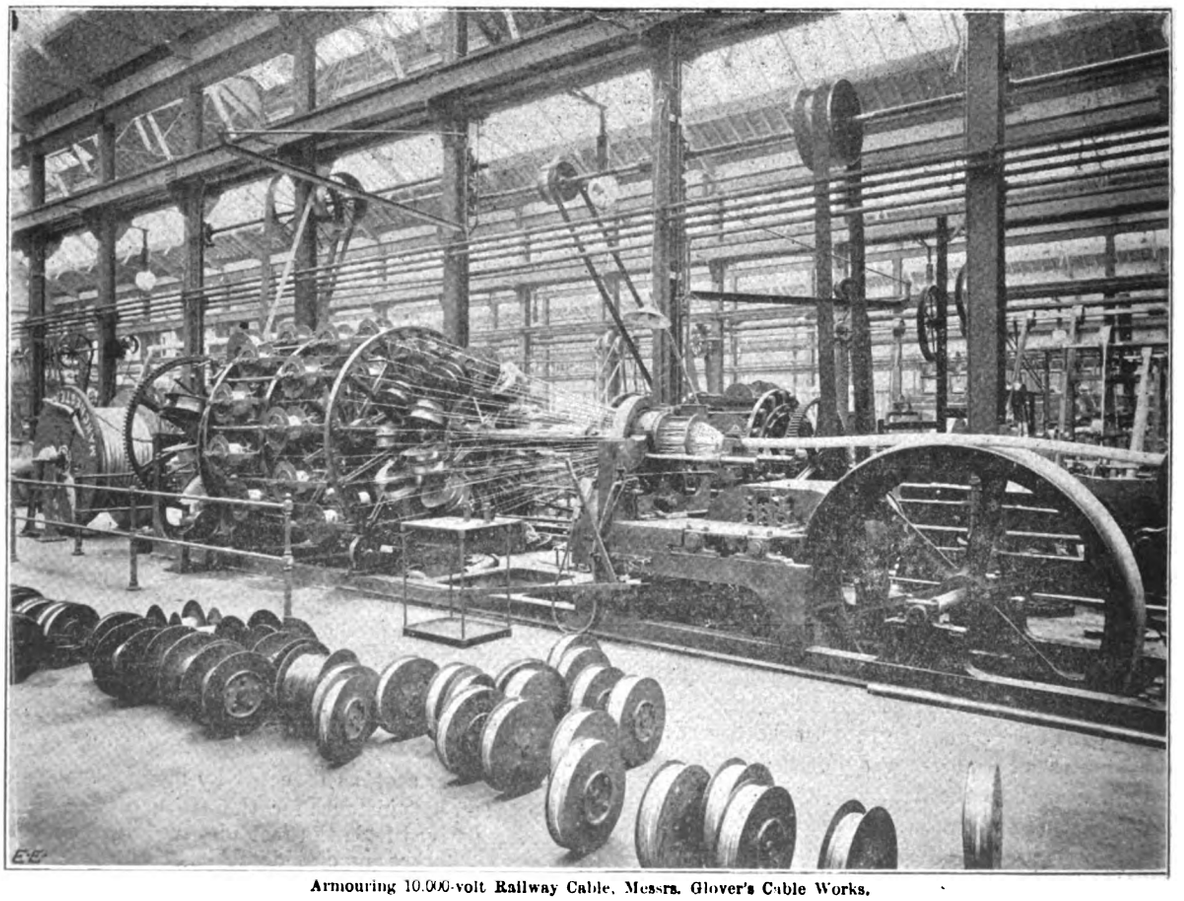
WORKS' VISITS.

III.—Messrs. W. T. Glover and Co, Limited, Trafford Park, Manchester.



Patent Hydraulic Testing Tank, Messrs. Glover's Cable Works.

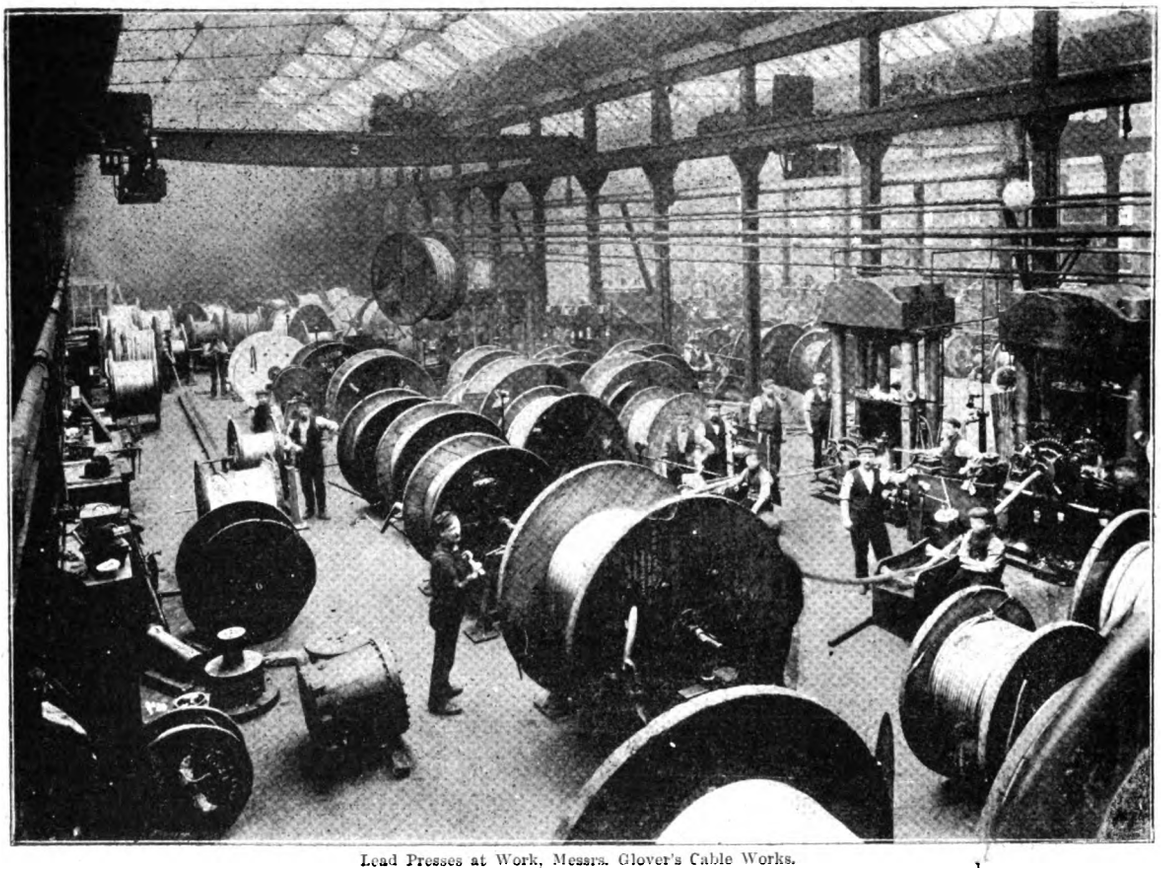
We have now to deal with works situated immediately opposite those described in the second article of this series. As specialists in the manufacture of electrical cables of all types and sizes, Messrs. Glover and Co. have won a world-wide reputation. Prior to making Trafford Park their headquarters the firm had obtained considerable experience in Salford, where they carried on the manufacture of electrical wire and cables with eminent success for a



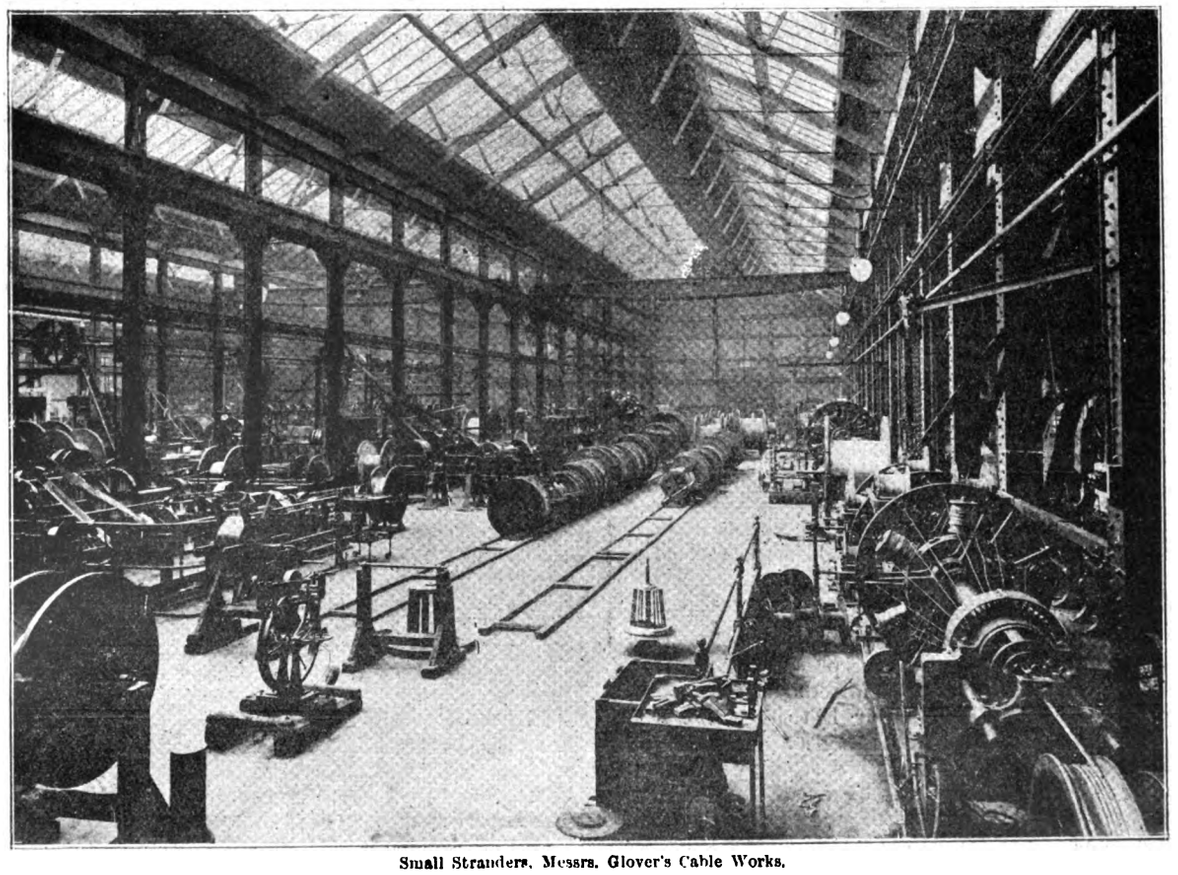
Armouring 10,000-volt Railway Cable, Messrs. Glover's Cable Works.

Digitized by Google

long term of years. This experience is reflected in the arrangement of their present works, than which, it can be said, none are better equipped for turning out the heavy class of electric cables used in connection with modern power and lighting schemes. These works have, however, been several times described, and it is not our intention to repeat well-known details here. It is rather to new additions to the equipment and productions of the works that we shall give our consideration. During a recent visit to the same our special attention was called to a hydraulic testing tank (Claremont's patent), shown in the first of the accompanying illustrations. This tank represents an essentially new departure, and may be destined to revolutionise present methods of testing lead-sheathed cables. There is little to say in regard to its construction beyond what is shown. It is made of boiler plates riveted together, and is designed to



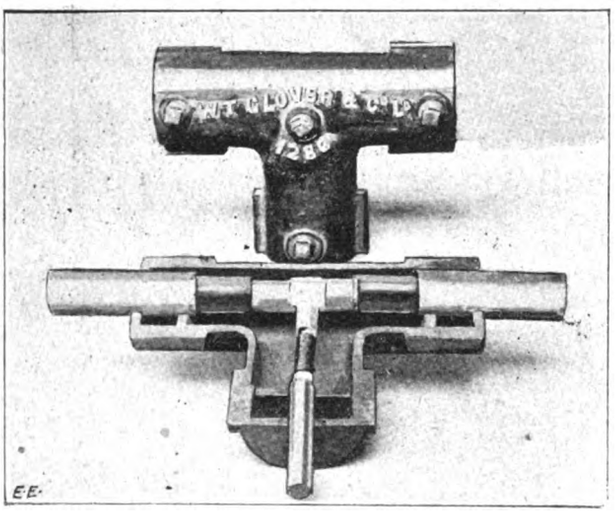
Lead Presses at Work, Messrs. Glover's Cable Works.



Small Stranders, Messrs. Glover's Cable Works.

Digitized by Google

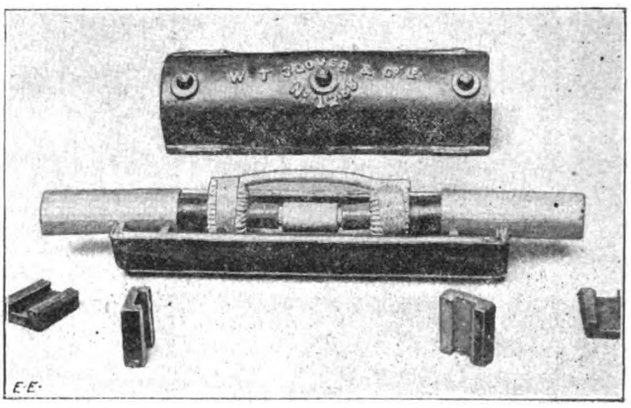
withstand a working pressure of 100lb. per square inch, ample margin being allowed for safety. Watertightness between the two halves of the tank is obtained with the aid of lead, which is pressed into a grooved fillet by the action of the tightening-up process, thus making a close joint. A set of hydraulic pumps furnishes the requisite pressure for testing. About 15 minutes is occupied by each test—that is to say, in enclosing a drum of cable, screwing down the cover of the tank, pumping it full of water and applying full pressure. It is found in practice quite unnecessary to maintain this pressure for more than a few seconds. The output of the tank, then, is largely governed by the speed at which it can be served. It is designed to take any drum up to 9ft. in diameter. When it is a question of testing smaller drums of cable, as many may be put in as the size allows. Roughly speaking, the capacity of this one tank measured over a given time is equivalent to that of about 30 ordinary tanks. In all, four men are required to serve the tank, including nut-pushers. The inception of the idea may be traced to the repeated failure of the usual method of testing to discover pinholes in the lead sheathing of cables, which, after 24 hours' immersion in an open tank, frequently give high insulation resistance, despite the existence of pinholes, this phenomenon being due to the non-hygroscopic quality of the paper insulation employed. In other words, besides being much quicker, careful experiments made by Messrs. Mordey and Dawbarn



Messrs. Glover's Single Cable Tee-Joint.

have shown this method to be more searching than the usual 24 hours' immersion in open tanks. Cables which after 24 hours' immersion withstood 1,000 volts broke down instantly at 500 volts after five minutes' immersion under pressure. And not only does the method instantly show the presence of any holes or cracks in the lead covering, but also breaks down incipient faults and weak places which under ordinary conditions would probably not be revealed until after the cable was laid. Naturally, some conservatism will have to be overcome before the new method is allowed to serve instead of the 24 hours' immersion test for lead-sheathed cables, but meanwhile it is satisfactory to Messrs. Glovers that several engineers have already recognised its efficiency and superiority.

Passing from the above described novelty, we made a rapid inspection of the rest of the works, of which some recent interior views are reproduced herewith. One branch, we noticed, was busily employed in making fireproof cables of a type recently introduced by Messrs. Glovers, and fully described in our last issue, pp. 889 and 890. Leather sheathing was being put on some of these cables, a patent method of protection, by virtue of which they are rendered doubly suitable for use in collieries. In fact, the leather braiding serves to give good mechanical protection to the cable without impairing its flexibility, the durable quality of the material itself making it peculiarly capable of withstanding the rough usage incidental to colliery work. The cost of providing this special protection is about the same as for steel armour, we understand. But when these fireproof cables are required for ordinary purposes, such as switchboard work, arc lamp leads, theatrical displays, railway work, etc., the leather braiding is omitted. We also saw the last instalment of the traction cable destined for use on the Lancashire and Yorkshire Railway—Liverpool and Southport line—in process of manufacture.

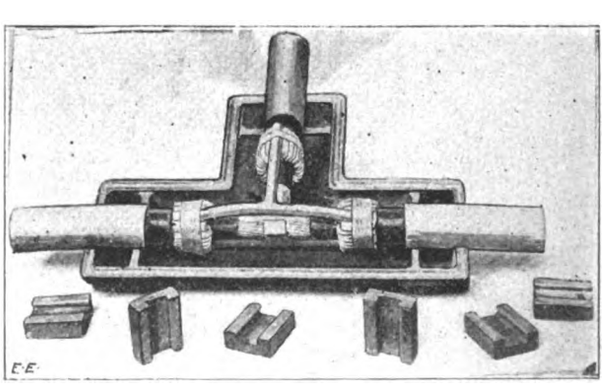


Messrs. Glover's Concentric Cable Straight Joint.

The special features of this important cable have been separately dealt with in a previous issue.

In addition, we noticed traction and lighting cables for about a dozen different municipalities, including Paisley, Sheffield, Blackburn, Bolton, Malvern, Darlington, Shipley, Stalybridge, and Wednesbury in different stages of progress, not to mention Government work, etc. With reference to the Stalybridge contract, it may be mentioned that this also includes cables for the neighbouring districts of Hyde, Dukinfield, and Mossley—thus four separate areas. These areas will be supplied from one central station under the control of a Joint Lighting and Traction Committee. The network of cables will also form one complete whole, the ownership being divided between the district councils representing the four areas in question. This scheme is noteworthy in that it shows what may be effected in small areas by unselfish co-operation.

An interesting feature likewise presents itself in connection with the cables which were being made to the order of the Wednesbury Corporation. This authority has contracted to take a supply of electricity in bulk from the Midland Electric Corporation. The Wednesbury Corporation are laying a twin concentric two-phase low-tension cable to connect their own sub-station with that belonging to the company, a matter of a few hundred yards distant. Why the municipal body should not have connected their distributing network directly with the company's sub-



Messrs. Glover's Concentric Cable Tee-Joint.

station, and thereby saved the cost of building and equipping a second sub-station, does not seem clear. This cable, termed by the makers "twin concentric," contains two inner cores with the common return of the two-phase system arranged concentrically round them. The cable is lead covered and armoured.

The last of the accompanying illustrations show Messrs. Glover's standard single-cable tee, concentric cable straight, and concentric cable tee methods of jointing, which may be

Digitized by Google

briefly described as follows: The single cables are connected together by a three-fingered fitting, which is clenched with gas pliers upon the main, the branch cable being sweated into a socket attached, the fitting being also sweated solid. The concentric cable inners are jointed on the straight by a sweating sleeve, and on the tee by the closing joint just described. The outer wires are turned back upon a cast sleeve, which has a groove at the top, into which fits a connecting rod, this and the outer wires being bound down together by No. 18 tinned copper binding wire and then sweated solid. The tee joint outer sleeves are in halves to save cutting the cable. It will be seen that these closing joints and concentric fittings make a very compact job, which is mechanically strong and of lasting conductivity. Also that the joint does not require a man of more than average intelligence and carefulness to make it satisfactorily, as its success depends more upon strength of fingers in clenching and binding than upon excessive accuracy of fit over the conductors. Messrs. Glover stock these joint-boxes and fittings largely to meet the demand that has arisen for them from corporation engineers and contractors all over the country.

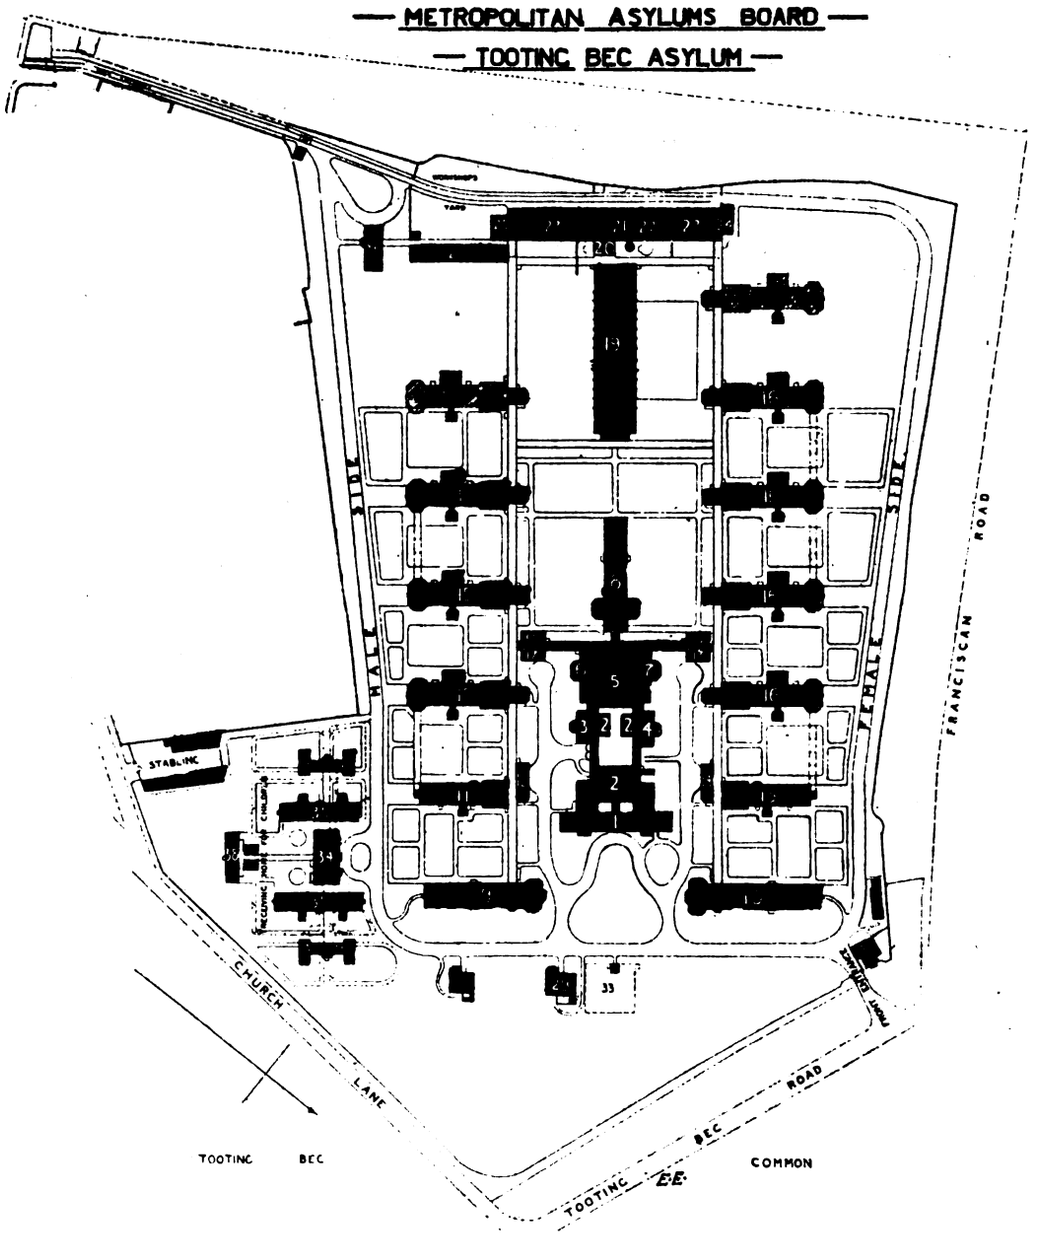


FIG. 1.—Block Plan of the Tooting Bec Asylum.

ELECTRIC LIGHTING AND POWER PLANT AT THE TOOTING BEC ASYLUM.

This latest addition to the undertakings of the Metropolitan Asylums Board was completed early this year, and provides accommodation for 804 patients. The general plan of the buildings is given in Fig. 1, which shows that two additional blocks are allowed for in the arrangements, which will raise the accommodation to nearly 1,000. The interest of our readers will lie in the engineering department, which is located in the buildings numbered 20, 21, and 22 respectively. These are the gas-producer house, the boiler-house, and the dynamo-house, with accumulator-room attached. The plant is novel in many respects for the class of building supplied, and this is particularly so with regard to the heating and lighting. Thus, while steam is used for heating, power gas is produced to drive the engines, which in turn drive the electric lighting dynamos. The wiring, too, is novel. The whole of this work was designed and carried out by Messrs. Handcock and Dykes, consulting engineers, of 1, Victoria-street, E.C.

The heating boiler house (Fig. 2) contains three steel Galloway type boilers, each 20ft. long by 6ft. 6in. diameter, and each capable of evaporating 3,800lb. of water per hour at a pressure of 80lb. These boilers serve to supply steam at 50lb. pressure for heating the various blocks, and at 80lb. pressure for use in the laundry and for the producer of the gasmaking plant. Each boiler is fitted with two mechanical stokers, supplied by the Underfeed Stoker Company, there being a motor-driven fan for supplying the forced draught. The coals used under these boilers are the screenings of the house coals supplied to the asylum. A Green's economiser of 72 pipes is arranged behind the boilers for the purpose of heating the feed water. In the pump-room there are two electrically-driven boiler feed

Digitized by Google

pumps, one of which is driven by a constant-speed motor, the pump itself having a link arrangement by means of which the length of the stroke can be varied to suit the output required from it, and the other being an ordinary pattern of three-throw pump direct-coupled to a motor, the speed of which can be varied over wide limits by driving it either across the outers of the three-wire system of mains at 240 volts, or across the neutral and outer at 120. In addition, each boiler is fitted with a Green and Boulding's "Buffalo" injector, and there is one steam-pump in reserve. The contract for the whole of the boiler-house equipment was let to Messrs. H. and T. Danks, Netherton, near Dudley.

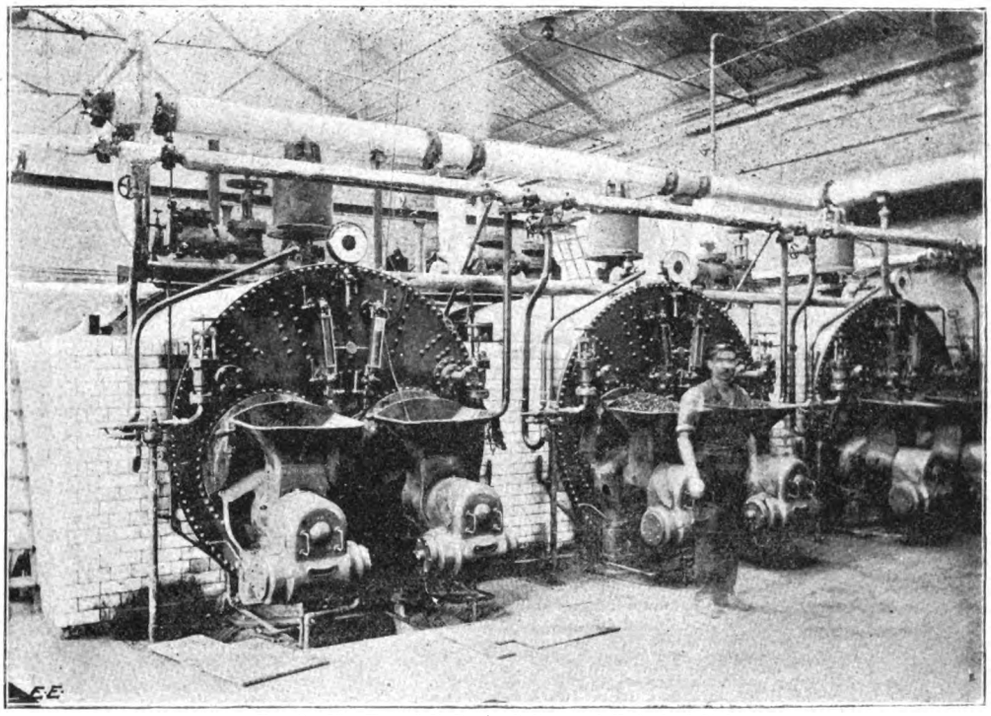

FIG. 2.—The H. and T. Danks Boilers and Underfeed Stokers.

The producer-gas plant was supplied by Messrs. Paisley-Welch, and consists of two of their gas-producers with the necessary scrubbers. After passing through the scrubbers the gas is led into a small regulating gasholder, and thence direct to the engines, the production of gas being controlled automatically by means of the rise and fall of the gasholder. This acts on a valve, which regulates the steam inlet to the producer. The process of making gas consists in blowing a jet of steam through a mass of red-hot anthracite coal contained in the producer, the gas, although of no use for illuminating purposes, being specially well adapted for use in gas-engines. During the trials made by the engineers on completion of the plant, the consumption of anthracite coal per electrical unit measured at the terminals of the dynamo amounted to only 1·4lb., whereas with steam plant this would have been at least 4lb. to 5lb.

The engine-room (Figs. 3 and 4) contains three Crossley gas-engines, each giving a maximum of 70 b.h.p. at about 210 revolutions per minute, and driving by belt a shunt-wound Crompton dynamo giving 140 amperes 250 volts at 550 revolutions. As a general rule, two engines only are in use, one being a stand-by. In addition to the three dynamos, there is a battery of accumulators (Fig. 5), consisting of 132 L B 9 Tudor cells, capable of discharging at 56 amperes for 10 hours at 240 volts, or, in other words, of supplying 1,000 16-c.p. lamps for 10 hours. This battery is used to run the lights during the night-time and during

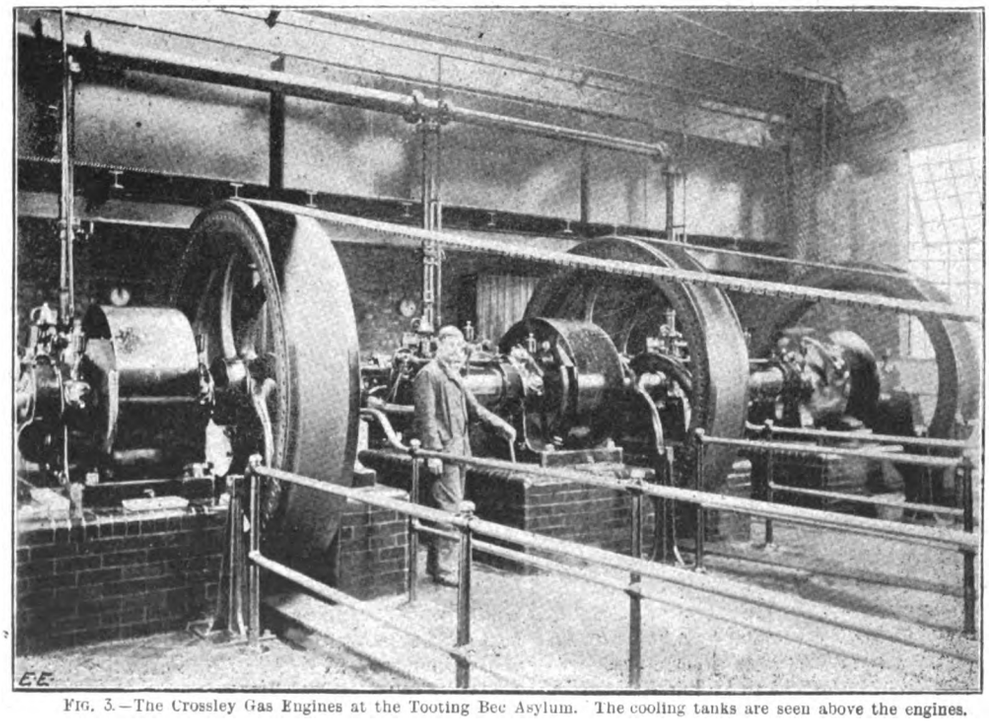

FIG. 3.—The Crossley Gas Engines at the Tooting Bec Asylum. The cooling tanks are seen above the engines.

Digitized by Google

parts of the day when there is no great call for current. The battery is charged by means of two boosters which are connected on to the shafts of the two balancing machines used to equalise the load on either side of the three-wire system. The battery connections to the main regulating switches being the switchboard are neatly made with bare copper wire, as shown in Fig. 5. The copper is protected from acid fumes by insulating enamel.

From the main switchboard, which is fitted with the usual instruments for measuring the output of the various dynamos and the current required on the different circuits, a main three-wire ring main is run right round the grounds in the subway connecting the various buildings. The lighting installation consists of about 2,300 incandescent lamps of 8 c.p. or 16 c.p. and 12 arcs for lighting the laundry, and has been carried out on a novel principle

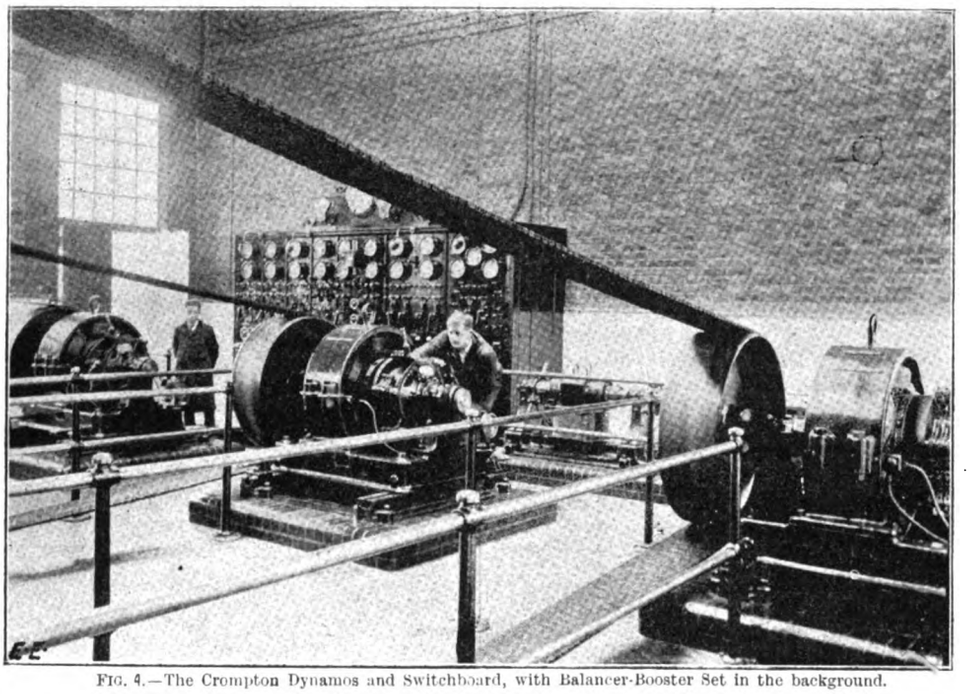

FIG. 4.—The Crompton Dynamos and Switchboard, with Balancer-Booster Set in the background.

In addition to supplying current for lighting, the generating plant also provides for a number of motors in various parts of the institution, there being two motors—one of 15 h.p. and the other of 5 h.p.—for driving the shafting in the laundry, a 10-h.p. driving a fan in the drying-room, a motor-driven pump at the far end of the grounds for pumping water from the rain-water tank

devised by the consulting engineers. This system, which may be called the draw-through concentric system, consists in running on the surface of the walls buried in the plaster small brass pipes varying from $\frac{5}{16}$in. to $\frac{7}{16}$in. internal diameter, and drawing into them a single or, in the case of a three-wire circuit, two insulated conductors. The pipe serves at the same time as a channel for and a

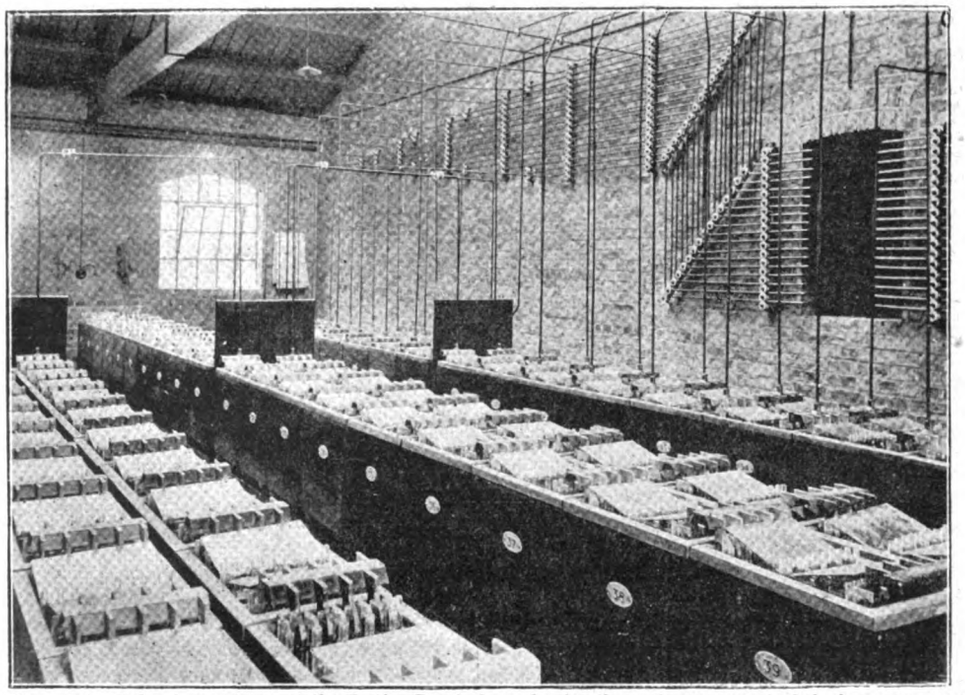

FIG. 5.—View of the Tudor Accumulators at the Tooting Bec Asylum, showing the neat arrangement of the bare copper connections.

for use in the laundry, and the various motors required for feed pumps, forced draught, and for working the scrapers of the economiser. The complete equipment of the electrical generating plant, including the producer-gas plant, gas-engines, dynamos, accumulators, main switchboard, and motors, was supplied by Messrs. Crompton and Co., of Chelmsford.¶

protection to the cable and as the return conductor for the current. One pole being thus connected to, and at the same pressure as, the earth, it is impossible to accidently obtain a shock, and only half the usual amount of wire is required. Owing to the small size of the pipes they can be laid in the thickness of the plaster without requiring to chase the walls, and by means of the system

Digitized by Google

of joint and switch boxes provided, any defective wire can be drawn in and out at any time without disturbing the plaster work or decorations; indeed, not a yard of wire was pulled into the pipe until the rest of the building was complete. Another advantage is that, when required for the purposes of cleaning or whitewashing, the whole of the fittings can be unscrewed, taken down, and put up again without breaking any joints or requiring any skilled labour. The lamps are supplied at 120 volts on the three-wire system, and there being, as stated above, a complete ring main, there are thus four circuits available for current, rendering it practically impossible for any breakdown of the main cable to put out more than half the lights at once. Each separate block has its own service box and main switch, by which it can be disconnected at any time from the ring mains, and all the fuses are grouped in distribution fuse-boards in the passages, there being not more than 10 lights on a circuit. The two sides of the three-wire system are practically balanced in each block.

The contract for the whole of the main cables, wiring, and fittings was carried out by Messrs. Robert Dawson and Co., of Stalybridge. The advantages of this system of wiring are many, and not the least is the fact that there is a continuous earthed metal sheath over all the live conductors. The fittings are interchangeable throughout, and screw into the terminal boxes with concentric connections. The architects for the above asylum were Messrs. A. and C. Harston.

INDEPENDENT TELEPHONY IN GREAT BRITAIN.

BY GARDNER AND HOLME.

(Continued from page 881.)

(8) Exchange Construction.

Another and important factor in the installing of the system is the construction and design of the exchange; in fact, as much, if not more, skill and experience is necessary as in the overhead and underground equipment. The exchange is the main spring of the whole undertaking, as upon it will depend the accurate working of the system and the service which can be given. Of late years the practice has been to secure premises quite inadequate for the purpose of giving a good service or of coping with the growth of the traffic. The utility and necessity of the telephone at a reasonable rate is now realised, and the requirements of a suitable building for the occupation of a switchboard and its accessories make it necessary to build specially for the purpose. The building itself should be designed to allow of offices, stores, operating, retiring, battery, test, and distributing rooms being in the same block; ample expansion being provided for future development, and all heating, lighting, fire, and ventilating appliances allowed for. Under the heading of exchange construction the fitting up of the operating, battery, and test room appliances first claims our attention. Owing to the rapid and continuous growth of the telephone industry in other countries, and the great bulk of the apparatus being obtained there, manufacturers in England have, unfortunately, found themselves unable to compete, so much so that at the present day there are few who have the plant and appliances necessary to turn out the apparatus for the equipment of modern test-rooms and large switchboards.

Modern Test-Rooms.—In the arrangement of the many devices and ideas that have from time to time been adopted we will confine ourselves to a general method. The lead-covered cables entering the test-room for distributing

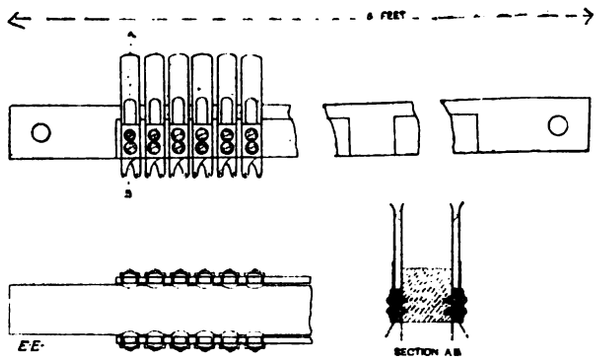

FIG. 45.—Test Jack.

purposes should be available for handling, and in order to effect this the cables terminate in what are termed pot-heads, these pot heads being arranged in order and directly in front of the frame, on the floor level. The paper cables being prepared by waxing, lacing, and taping up ready for soldering on to the test jack strips, which are mounted on the frames. The design of the frame might be after the manner we adopted as shown in Fig. 44, the size being in accordance with the ultimate capacity of the cables proposed to be laid down. To this frame are fitted the strips of test jacks, each numbered from 1 to 100, and mounted on highly insulated wood, as shown in Fig. 45, each individual jack being independently insulated by vulcanite blocks and washers, provided with soldering tags for the reception of the dry-cored paper cable wires. This method of terminating is simple, substantial, and effects a considerable saving over other methods which

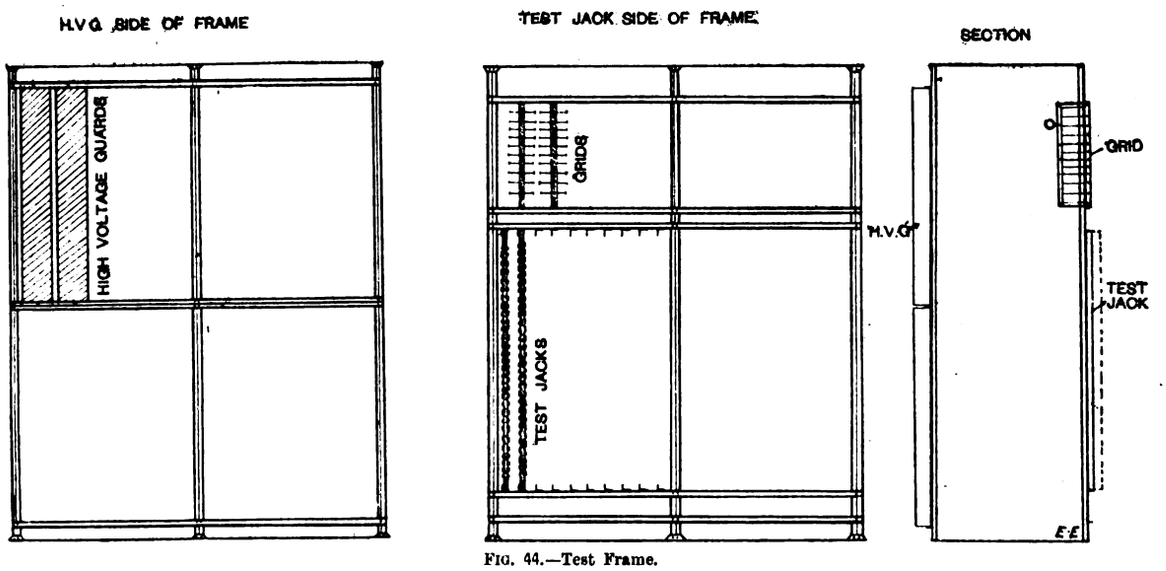

FIG. 44.—Test Frame.

have been tried. Upon the other side of the T iron frame, or what we might term the switchboard side, are erected the arrester strips, again mounted in rows or strips of 100 each (five sets of 20), as will be seen from Fig. 46, being also numbered from 1 upwards. From the arrester, or switch-board, side of the frame paraffined cables can be run to an intermediate distributing frame. From the intermediate distributing frame the paraffined cables are conveyed in ducts to the main switchboard. These cables are generally of 42 wire No. 22 S.W.G., and, if mechanically protected in good strong wood conduits under the floor, need not be lead covered, as it is sometimes the practice. The advantages

Digitized by Google

and simplicity of arranging the incoming cables and frames in this manner become apparent, but, on the other hand, arguments might be brought against such a practice, in that no protection is given to the cross-connecting wires on the line side of the distributing frame. That is so where the test and arrester frames are constructed of wood and the cross connecting wires are rubber and paraffined cable, but with frames constructed entirely of iron and fireproof, and the cross-connecting wire asbestos covered, no fear need be anticipated in that direction. It must also be remembered that if the cables are taken directly on to the safety 100. All the combined parts which go to make up a switchboard equipment should be mounted in such a manner that will allow of any one part being removed from the back or front of the board without disturbing the remaining parts and cables in any way either in the taking out or replacing. The design and mounting of the spring jacks and indicators should be done in such a manner as to render them self-contained and readily adjustable at any time. When it is desired to adjust, repair, or clean the various parts, provision should be made to quickly effect this, so as not to disturb the working of the board.

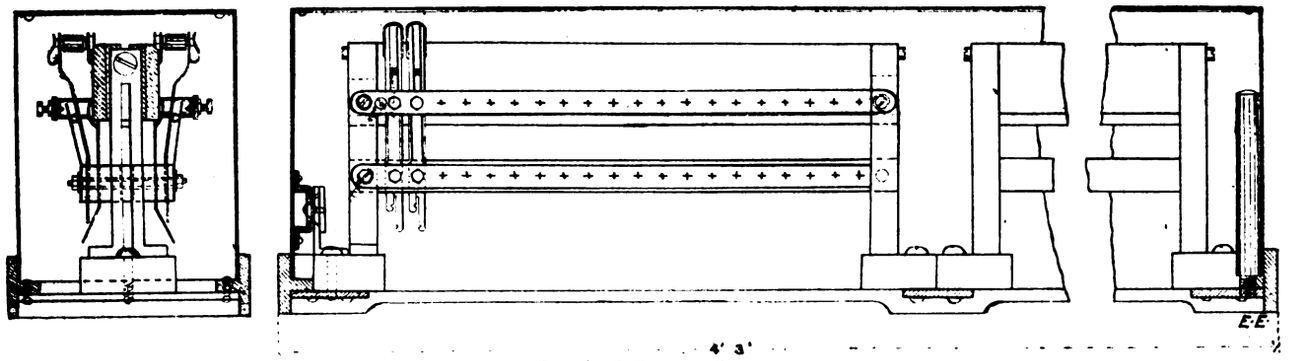

FIG. 46.—Switchroom Guard.

arrester frames a greater number of arresters would be required to accommodate the spare cable wires, which must necessarily and generally are provided for extensions and the growth of the system. This item alone is an expensive one, and ought to be carefully considered when planning out the preliminary arrangements in test-rooms. In designing the frames, provision should be made for the conveyance for the cross-connecting wires in their proper order, and also that access can be given to the removal and transposition of any wires, without interfering with the others. This in a large exchange is a great matter, as numbers are constantly being changed.

Another and important matter, and one which is very often lost sight of, is the amount of spare accommodation to leave in the frame for future development, and by adding combined jacks and indicators in the local field, and multiple jacks in the multiple field as the system expands, due provision being made in the wiring of the local and multiple cables to effect these additions.

Framework.—A rigid angle-iron structure makes the best frame for large multiple switchboards, the objections to wood being the inaccessibility to the various parts through the battens or wood supports being necessarily large, in order to take the weight and strain of the cables and

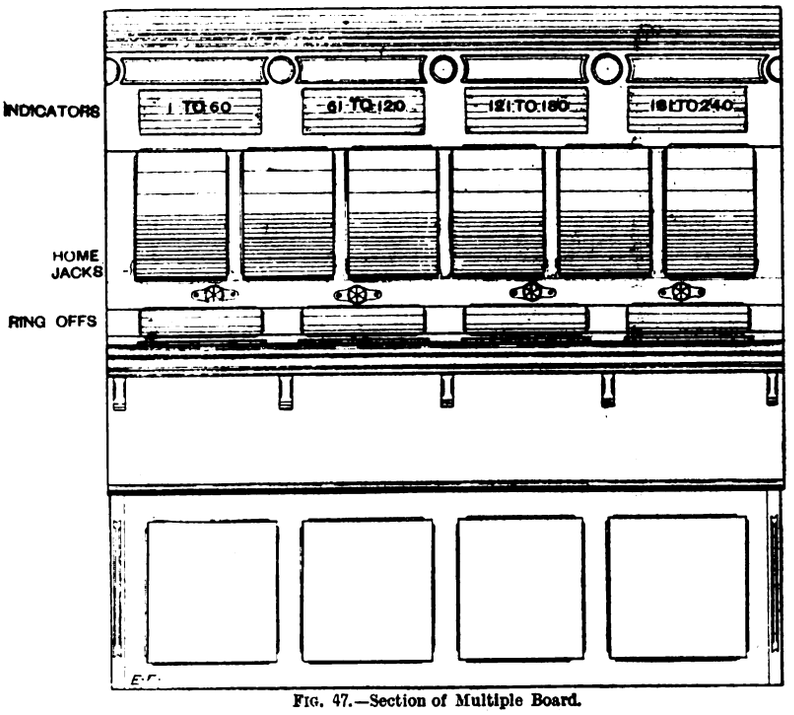

FIG. 47.—Section of Multiple Board.

Switchboard Fitting.—In the designing of switchboards for exchange working many points and circumstances have to be taken into account. These circumstances will vary according to the number of lines to be provided, the system which is intended to be adopted, and also the most suitable for the district, the number of junction lines which will be operated between the various exchanges and Post Office, the number of calls which are likely to be handled, and the number of lines which it is intended to assign to each operator. Assuming that low tariff rates are to be adopted with a toll service, the number of lines to be apportioned to each operator's position could be with

fittings. In the design and setting off of the iron frame great care must be exercised in the drilling and tapping of the various centres. Fig. 47 gives a general idea of one section of a multiple board manufactured by the British Insulated and Helsby Cables Company, Limited.

Self-Contained Indicators and Jacks.—On reference to Fig. 48 it will be seen these are self-restoring, and the jacks and coils are directly placed in the local field in front of the operator, the indicator being restored by actual mechanical contact with the plug. The jacks should be of the very best German-silver springs, rigidly mounted and lightly insulated on strips of vulcanite, and so bolted and

Digitized by Google

braced as to prevent warping. The coils being carefully wound to the desired and proper resistance on highly insulating bobbins, and not on the iron cores of the indicator, as is generally the practice, the relay or night-bell circuit being kept independent and absolutely clear of the frame of the indicators or coils.

Ring-Off Indicators are of the differentially-wound tubular type, one drop being provided with each pair of cords, the drops being wound to 1,500 ohms (each winding), and in such a manner as to be absolutely non-inductive no matter what pair of cords are used.

Keys.—Ringing, speaking, and clearing out keys of a thoroughly reliable pattern should be provided, and fitted in the front of the board in a readily accessible manner, one for each pair of plugs. These should be so constructed that a backward movement upon the lever enables the operator to speak on the cord circuit, and a forward movement from the operator throws the calling or power generator on to the calling plug. The lever being arranged to always return to the normal position automatically, when released from either speaking or ringing position, to the ring-off or clearing circuit and cut the plug connection of the through circuit should the operator attempt to break in. All springs should be constructed of the best German silver, platinum pointed to prevent corrosion, and be long, so as to prevent possibilities of weakness setting up after being in use for any length of time.

Plugs and Connecting Cords.—No one has yet been able to place upon the market an ideal switchboard plug and cord, although many ideas have from time to time been tried and adopted. The plug and cord being the hardest worked part of the whole apparatus, it is essential that they be constructed of the very best material which can be obtained. All plugs, whether two or three way, should be substantially made of perfect gauge to fit the jacks, and be provided with

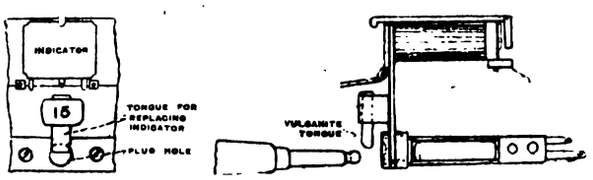

FIG. 48.—Combined Indicator and Jack.

screw connections for the cord strands. Over the connections polished hard fibre sleeves should be slipped to serve as a protection, and a handle for the operator. The conductors of the core strands should be of tinsel, with a stranded core of very fine copper wire thoroughly insulated and protected, all the insulated conductors being closed in a spiral wrapping of spring brass wire to form an armouring for the conductors within. Over this a heavy linen braid should be woven single the entire length and double at each end of the cord for about 6in. This lessens the chance of breakage at the point where the strain is greatest.

Generators.—Hand generators should be provided and fitted to the board ready for use in case of breakdown to the power set. These should be capable of ringing through 50,000 ohms and be provided with noiseless hand driving gear and automatic cut-in worked from the spindle of the driving gear. This prevents any possible chance of the generator being shunted through another.

Operators' Sets.—To each operator's position should be fitted an induction coil of the bridged type, a five-point jack mounted on a vulcanite block, wired ready to receive the stranded flexible cord and plug for the connection to the receiver and transmitter.

Wiring.—The very best of switchboard cable should be used, made up and formed of No. 22 copper wire. To the operators' microphone sets and all power circuits, special highly insulated-rubber twisted twin wires should be used of proper sizes to ensure the carrying capacity on the circuits. The entire switchboard system deriving its current from storage batteries, it is essential to see that these circuits are run in a careful manner and clear of all other wiring on the board. For the reception of these circuits distributing boards should be provided and mounted in each section. These distributing boards, consisting of an enamelled slate base upon which are mounted brass terminals for the various circuits, are as follows: operator's microphone, generator, night-bell relay or pilot circuit, and main calling circuit.

(To be continued.)

THE GILBERT TERCENTENARY CELEBRATION.

As it happened, the usual fortnightly meeting of the Institution of Electrical Engineers in London on Thursday evening, the 10th inst., fell on the three hundredth anniversary of the death of Dr. Wm. Gilbert, of Colchester, and in celebration of the interesting and historic occasion the Council devoted the first part of the meeting to formally presenting to the Mayor and borough of Colchester a picture representing Dr. Gilbert showing his electrical experiments to Queen Elizabeth and her Court. The painting, of which we give the accompanying illustration, is the work of Mr. Acland Hunt, and was subscribed for by the Council and members of the Institution. It bears the inscription: "Presented by the Institution of Electrical Engineers to the Corporation of Colchester in commemoration of the scientific achievements of Dr. Gilbert, on the 10th of December, 1903, the three hundredth anniversary of his death."

The Mayor of Colchester (Mr. E. H. Barritt) attended in state, accompanied by three other members of the Corporation and the Town Clerk; and there were also present in addition to Mr. R. Kaye Gray (the president) and the members of the Council, the Mayor of Westminster (Mr. Walter Emden), the President of the Royal Society (Sir Wm. Huggins), the President of the Société Internationale des Electriciens (Mons. E. Hospitalier), the Treasurer of the Royal College of Physicians (Sir Dyce Duckworth, M.D.), Dr. J. Larmor, F.R.S., of St. John's College, Cambridge (Dr. Gilbert's College), and the Borough Electrical Engineer of Colchester (Mr. A. R. Sillar).

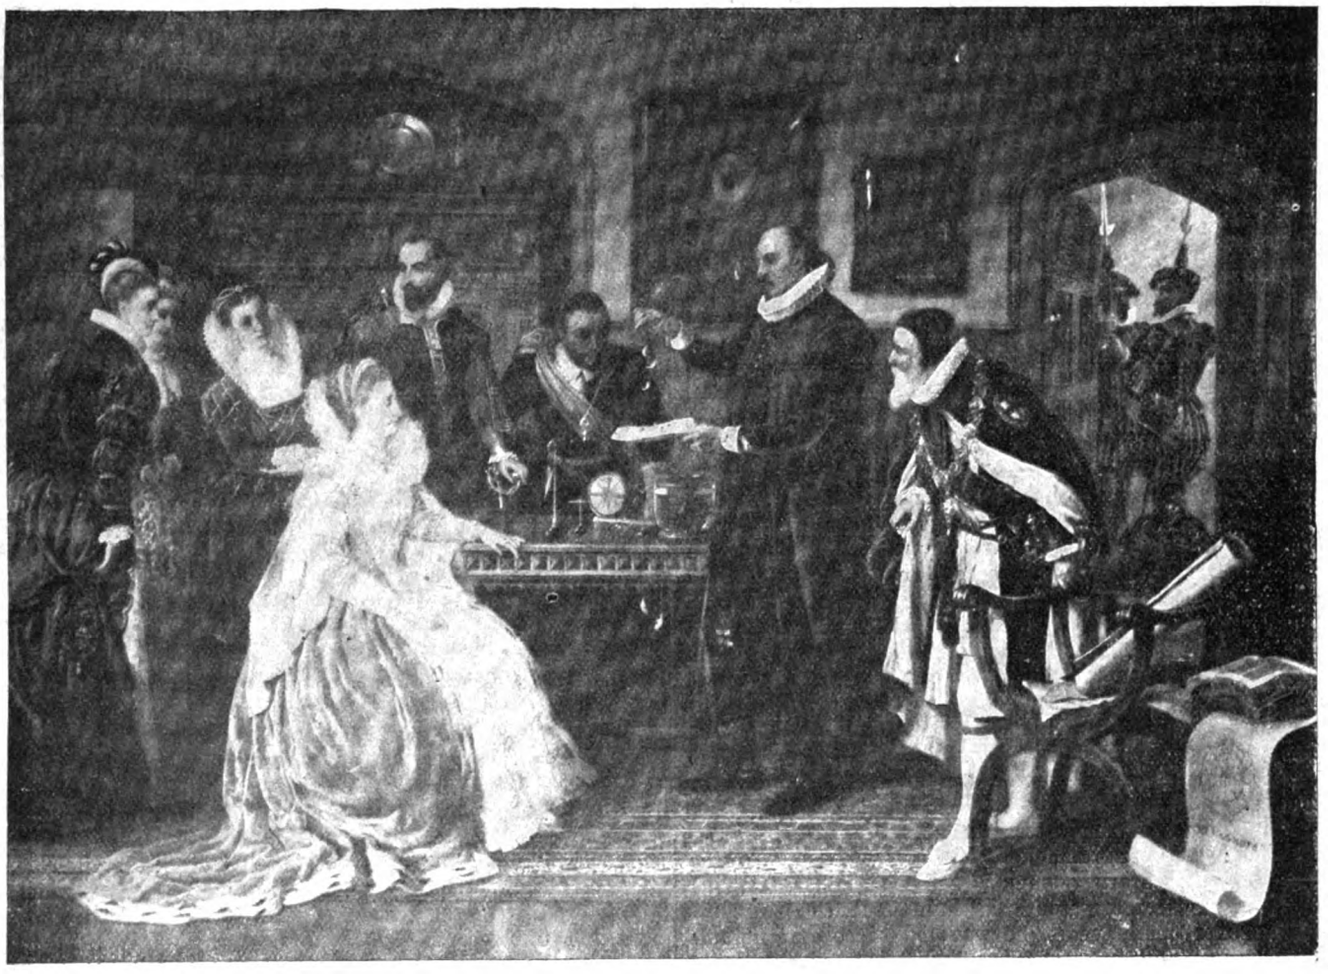
The PRESIDENT, in opening the proceedings, explained that they had met there that night to ask the Mayor of Colchester to be kind enough to accept in the name of the Institution the picture which they saw before them. They all knew something about Dr. Gilbert, but he would leave it to Prof. Silvanus Thompson, who was much more competent to deal with the subject than he, to tell them the particulars of the presentation. Prof Silvanus Thompson and Mr. Conrad Cooke were the two honorary secretaries of the Gilbert Society, and they had both worked very hard in the cause of commemorating the work of Dr. Wm. Gilbert. It would be unbecoming in him, therefore, to say much on this subject, and, therefore, he would simply conclude by asking Prof. Thompson to make a few remarks.

Prof. SILVANUS THOMPSON said he had in the first place to read a portion of a letter received from Lord Kelvin, who regretted very much his inability to be present that evening owing to an engagement in Scotland. Lord Kelvin thought the plan that had been hit upon for the commemoration of Gilbert a good one, and he sent his apologies that he could not take part in the proceedings. Mr. Acland Hunt, the painter of the picture, desired it to be known that he had spent very many years on the painting as a labour of love, but that he was incited to the idea by the late Sir Benjamin Richardson, and had laboured to be faithful even with the best that could be done in the way of portraiture to bring back the episode it commemorated. They, as electricians, owed an enormous debt of gratitude to Dr. Gilbert. There were many great men in the time of Queen Elizabeth, but for electricians Gilbert stood out pre-eminent. It was true that there were statesmen before Cecil, naval heroes before Drake, explorers before Raleigh, dramatists before Shakespere, poets before Spencer, and philosophers before Bacon, but before Gilbert there was no electrician. He was the absolute founder of electricity, and he claimed their admiration not only as the founder of the science of electricity, but as the founder also of another science—that of terrestrial magnetism. They all knew how he devoted the greater part of his activities and no less than £5,000, according to Harvey, or according to Decarte, 5,000 crowns, to this science, and how in 1600 he produced his book, the identical copy of which he (Dr. Thompson) held in his hand, and which the author had presented to

Digitized by Google

Lancelot Brown, another physician to Queen Elizabeth. In this book Gilbert laid the foundation of terrestrial magnetism, proceeding by the at that time little recognised method of experiment. Gilbert used a little ball of loadstone, and by placing a compass needle over it and seeing how it pointed he was able to show that the variations, the tipping, and the pointing of the needle were identical with those of a needle over the surface of the earth, and he was laid out that new and unheard-of idea that the earth itself a great magnet, That was the text of this book. Not only did Gilbert found the science of terrestrial magnetism, but also contributed to the science of astronomy, and the science of navigation. It was therefore fitting that when they were met together to commemorate the three hundredth anniversary of his death they should have with them representatives of other bodies which represented scientific progress in this country. These representatives they were all delighted to welcome. One fact must not be forgotten. Like Lancelot Brown, Gilbert was a Fellow of St. John's College, Cambridge. He was even mathematical examiner and senior bursar. Also, it must be stated Gilbert was born at Colchester on May 24, 1544, at 2.30 p.m., in a house which was still standing, and to which he returned in his later years, and, for aught they knew, died there. That house was the very Mecca to which all electricians would go to make a pilgrimage, and within a short distance of it, across the street, lay his bones in the churchyard of St. Trinity. In the new church there was a fine heraldic monument to his memory which recorded his virtues and his career. Prof. Thompson, in conclusion, said he had tried to tell the tale of the hero at whose shrine he worshipped, and he hoped many of them would have the opportunity of repairing to Colchester that they might worship at his tomb.

The PRESIDENT then presented the picture, formally asking the Mayor of Colchester, in the name of the Institution, "to be kind enough to accept and keep in your safe keeping for your town and Corporation the picture you see before you."



Dr. Gilbert showing his Electrical Experiments to Queen Elizabeth and her Court.

The MAYOR OF COLCHESTER, returning thanks on behalf of his town, said that the kind words which had been spoken by Dr. Thompson, promoted by the even kinder motive which lay behind those words, were calculated to deeply stir the feelings of a man much older than himself. It was about a month ago that he received a letter from Dr. Thompson asking him in a simple, artless manner whether in the event of any tercentenary celebration being held in London he might possibly be able to attend. He was obliged to own that his thoughts turned to a dinner, but he determined that whatever form that celebration might take, out of respect to the memory of Dr. Gilbert, in honour of the services he rendered to electricity and magnetism, and as the representative of his native town—the borough in which Gilbert lived and worked and died—he should be glad to attend. He rejoiced that the Institution of Electrical Engineers had not stooped to any form of celebration so trenchant, so mundane. He would say a word or two about himself in order to assure them that their gift passed into safe hands, and that it would remain in safe keeping until in his turn he handed it over to his town. About 27 years ago he learnt to reverence the name of Gilbert. It was then, at the age of 13, that he obtained a prize in electricity and magnetism at South Kensington, and, call it a coincidence if they would, that prize was now the favourite book of his only child—a boy of 6½ summers. He remembered when quite a boy going down to the church of Holy Trinity to see the tablet erected to the memory of Dr. Gilbert, and how he was turned out by the gardener without his desire being gratified. He remembered well his first revolving plate electrical machine, and he took even more interest in watching the glass plate revolve than in watching the revolutions of the 550-kw. generator at the Colchester electricity works to-day. He remembered his first Leyden jar—his difficulty in fixing the inner coating of tinfoil, and how he finished the apparatus with a wire and wooden knob covered with foil. He remembered his battery of six Leyden jars; he remembered his first shock

Digitized by Google

from them, and then for a time he remembered little more. He never thought how those early struggles were destined to play their part in qualifying him for the position of chairman of the electricity department of the Colchester Corporation to-day; how in the higher office of mayor he should be invited to attend that historic gathering that night, and receive at the hands of the President of the Institution so unique a gift. Colchester had learnt to reverence the name of Gilbert. The Institution of Electrical Engineers had in its wisdom, in its love, and in its devotion to his memory, seen fit to secure this valuable and historic painting, and having secured it to present it a gift to Gilbert's native town. First among the many pleasing recollections associated with the opening days of his mayoralty would rank the knowledge that he was privileged to attend this celebration, to be the recipient at the hands of such donors of so generous a gift. The painting should find a fitting resting place on the walls of Colchester Town Hall, which henceforth would become its home.

The PRESIDENT proposed a vote of thanks to the Mayor of Westminster and the representatives of the various scientific bodies present, which was carried by acclamation, and the MAYOR OF WESTMINSTER and Sir DYCE DUCKWORTH (treasurer of the Royal College of Physicians) having returned thanks, the ceremony ended.

We hardly suppose that there is an electrical engineer to-day who is not familiar with the name of Dr. Wm. Gilbert or with his wonderful achievements as the "Father of Electrical Science." Dr. Silvanus P. Thompson, as our readers know, has taken up the subject as a special study, and it was natural that to him should be allocated the responsibility of preparing some notes on the life and career of Gilbert for publication on the occasion of the tercentenary celebration. Dr. Thompson in these notes traces the foundation of the electrical science to the publication in 1600 of the "De Magnete" of Dr. Gilbert. In a short introduction he says: "Gilbert's renown rests not on his eminence as a physician, but on his achievements in the foundation of the twin sciences of electricity and magnetism. He is beyond question rightfully regarded as the father of electric science. He founded the entire subject of terrestrial magnetism. He also made notable contributions to astronomy, being the earliest English expounder of Copernicus. In an age given over to metaphysical obscurities and dogmatic sophistry, he cultivated the method of experiment and of reasoning from observation, with an insight and success which entitles him to be regarded as the father of the inductive method. That method, so often accredited to Bacon, Gilbert was practising years before him. It seems, therefore, fitting upon the occurrence of the tercentenary of his death to recall Gilbert's achievements as the father of electric science."

Dr. Thompson thus describes Gilbert's magnetic discoveries: "Gilbert's magnetic work has been so often described that a brief summary will here suffice. Trying the properties of loadstones in innumerable experiments lasting over many years, he was led to several notable discoveries, and to one generalisation of immense importance. He discovered the augmentation of the power of a loadstone by arming or capping it with soft iron cheeks. Gilbert called such a cap an *armatura*, the first occurrence of the term. This invention brought him much fame. In the 'Dialogues of Galileo' (p. 369 of Salusbury's 'Mathematical Collections,' Dialogue iii.), Sagredus and Salviatus discuss the arming of the loadstone, and the increased lifting power conferred by adding an iron cap. Salviatus mentions a loadstone in the Florentine Academy, which, unarmed, weighed 6oz. lifting only 2oz, but which when armed took up 160oz Whereupon Galileo makes Salviatus say: 'I extreamly praise, admire, and envy this authour for that a conceit so stupendious should come into his minde. . . . I think him [*i.e*, Gilbert], moreover, worthy of extraordinary applause for the many new and true observations that he made, to the disgrace of so many fabulous authours, that write not only what they do not know, but whatever they hear spoken by the foolish vulgar, never seeking to assure themselves of the same by experience, perhaps, because they are unwilling to diminish the bulk of their books.'

"Gilbert also discovered the screening effect of a sheet of iron; the method of magnetising iron by hammering it while it lies north and south; the destruction of magnetism by heat; and the existence around the magnet of an 'orbe of virtue'—that is to say, a magnetic field. He perfected the dipping needle of the Norman and other instruments of observation. He collected data as to the declination and inclination of the compass in different regions. Using loadstones of many different shapes, he observed their actions on one another and on compass needles. In particular he studied the magnetic properties of a globular loadstone or *terrella*, and found that compass needles were directed toward its poles, and dipped at various angles over its surface, just as compass needles do at various regions of the earth's surface.

"Generalising from small to large, he advanced the entirely novel idea that the globe of the earth is itself a great magnet, thus laying the foundations of the science of terrestrial magnetism. He was particularly keen in disproving the many absurd fables that had grown up about the magnet, such as that the magnet refuses to act in the presence of a diamond, or if touched with garlic. The former he tested by surrounding a loadstone with 70 diamonds. Gilbert denounced the quackery of using loadstone medicinally or in plasters for the cure of wounds. He ridiculed the idea that the variation of the compass was due to imaginary loadstone mountains like those described in the 'Arabian Nights.' He sought to explain it by the local irregularities of the earth's crust, and exemplified his theory by experiments on round loadstones of irregular outline as models. His book, over which he spent 18 years, was published in 1600, and for the next 100 years became the standard work on magnetism. Though denounced by the Church, the theory of terrestrial magnetism was by Gilbert thus firmly established on an enduring basis of fact, and remained a permanent acquisition in science. The publication of the book marked an epoch in scientific development. It was praised by Sarpi, by Galileo, by Kepler. Sir Christopher Wren proposed to erect a statue to its author, while Dryden sang of his enduring fame."

The contribution made by Gilbert to electrical knowledge is contained in the second chapter of the second book of his "De Magnete," and constitutes a digression interpolated into the discussion of magnetic motions. In this chapter Gilbert, after describing the attracting properties of amber, lays down the following maxims: "The difference between magnetics and electrics is that all magnetics run together with natural forces; electrics only allure; that which is allured is not changed by an implanted force, but that which has moved up to them voluntarily rests upon them by the law of matter. Bodies are borne towards electrics; a loadstone draws a loadstone directly at the poles only, in other parts obliquely and transversely, and in this way also they adhere and hang to one another. Electrical motion is a motion of aggregation of matter; magnetical motion is one of disposition and conformation. The globe of the earth is aggregated and coheres by itself electrically. The globe of the earth is directed and turned magnetically; at the same time also it both coheres, and in order that it may be solid, is in its inmost parts cemented together."

Dr. Thompson supplies the following valuable summary of Gilbert's electrical work: "To distinguish his original discoveries from things already known, Gilbert set in the margin of his book asterisks, large or small, in proportion to the importance of the matter. . . . He marked with large asterisks the discovery of the generality of electrifiable bodies, for which he coined the name *electrics*, and the observation that electrified bodies attract not straws and chaff only, but equally attracts metals, woods, earths, and even oil and water. The logical outcome of this discovery was the invention of the versorium or *electroscope*. The method of trying everything instead of accepting statements on authority is characteristic of the man: he must bring all to the touchstone of experiment. The authors who raised Gilbert's wrath by ignorantly copying out all the old tales about amber, jet, and loadstone, instead of investigating the facts, were, as he says at the beginning of the chapter, some theologians and some physicians. He seems to have taken a special dislike to Albertus Magnus, to Puteanus, to Paracelsus, and to Levinus Lemnius.

Digitized by Google

Gilbert mentions amber and jet as known to become electrical by friction; but the list was not quite so restricted as would appear from this passage. Five, if not six, other minerals had been mentioned, in addition to amber and jet."

The stones referred to by Dr. Thompson are lyneurium, ruby, garnet, jasper, lychnis, and diamond. Referring to the passage in Gilbert's book, in which he sets forth the differences that exist between magnetic and electric effects, Dr. Thompson says: "Though Gilbert was the first systematically to explore the differences that exist between the magnetic attraction of iron and the electric attraction of all light substances, the point had not passed unheeded, for we find St. Augustine, in the "De Civitate Dei," liber xxi., cap. 6, raising the question why the loadstone which attracts iron should refuse to move straws. The many analogies between electric and magnetic phenomena had led many experimenters to speculate on the possibility of some connection between electricity and magnetism. See, for example, Tiberius Cavallo, "A Treatise on Magnetism," London, 1787, p. 126. Aepinus wrote a treatise on the subject, entitled "De Similitudine vis Electricæ et Magneticæ" (Petropolis, 1758). This was, of course, long prior to the discovery by Oersted in 1820 of the real connection between magnetism and the electric current. It is interesting to note a suggestion of material *rays*, as the operation of electric forces seems to foreshadow the notion of electric lines of force.

"Gilbert had imbibed the schoolmen's ideas as to the relations of matter and form. He had discovered and noted that in the magnetic attractions there was always a verticity, and that in the electrical attractions the rubbed electrical body had no verticity. To account for these differences he drew the inference that since (as he had satisfied himself) the magnetic actions were due to *form*—that is to say, to something immaterial—to an "imponderable," as in the subsequent age it was called—the electrical actions must necessarily be due to *matter*. He therefore put forward his idea that a substance to be an electric must necessarily consist of a concreted humour which is partially resolved into an effluvium by attrition. His discoveries that electric actions would not pass through flame, whilst magnetic actions would, and that electric actions could be screened off by interposing the thinnest layer of fabric, such as sarcenet, whilst magnetic actions would penetrate thick slabs of every material except iron only, doubtless confirmed him in attributing the electric forces to the presence of these effluvia. There arose a fashion, which lasted for over a century, for ascribing to 'humours,' or 'fluids,' or 'effluvia,' physical effects which could not otherwise be accounted for.

"In spite of his care to test everything by experiment, Gilbert fell into several errors. He denied the existence of electric repulsion, and whilst he strenuously affirmed that the magnetic forces were mutual between the magnet and the iron, each being urged toward the other, he also affirmed that, in the case of the action of the electric on the object which moved toward it, the action was not mutual, but was a one-sided force—an impossibility in physics. Gilbert's experimental discoveries in electricity may be summed up as follows: (1) the generalisation of the class of *electrics*; (2) the observation that damp weather hinders electrification; (3) the generalisation that electrified bodies attract everything, including even metals, water, and oil; (4) the invention of the non-magnetic *versorium* or electroscope; (5) the observation that merely warming amber does not electrify it; (6) the recognition of a definite class of *non-electrics*; (7) the observation that certain electrics do not attract if roasted or burnt; (8) that certain electrics when softened by heat lose their power; (9) that the electric effluvia are stopped by the interposition of a sheet of paper or a piece of linen, or by moist air blown from the mouth; (10) that glowing bodies, such as a live coal, brought near excited amber discharge its power; (11) that the heat of the sun, even when concentrated by a burning mirror, confers no vigour on the amber, but dissipates the effluvia; (12) that sulphur and shellac when aflame are not electric; (13) that polish is not essential for an electric; (14) that the electric attracts bodies themselves, not the intervening air; (15) that flame is not attracted; (16) that flame destroys the electrical effluvia; (17) that during south winds and in damp weather, glass and crystal, which collect moisture on their surface, are electrically more interfered with than amber, jet, and sulphur, which do not so easily take up moisture on their surfaces; (18) that pure oil does not hinder production of electrification or exercise of attraction; (19) that smoke is electrically attracted, unless too rare; (20) that the attraction by an electric is in a straight line toward it.

"Gilbert's list of electrics should be compared with those given subsequently by Cabeus (1629), by Sir Thomas Browne (1646), and by Bacon. The last-named copied out Gilbert's list almost without change. Sir Thomas Browne's list is given in the following passage, which is interesting as using for the first time in the English language the noun *electricities*: 'Many stones also both precious and vulgar, although terse and smooth, have not this power attractive; as Emeralds, Pearle, Jaspis, Corneleans, Agathe, Heliotropes, Marble, Alablaster, Touchstone, Flint, and Bezoar. Glasse attracts but weakely though cleere, some slick stones and thick glasses indifferently: Arsenic but weakely, so likewise glasse of Antimony, but Crocus Metallorum not at all. Saltes generally but weakely, as Sal Gemma, Alum, and also Talke; nor very discoverably by any frication: but if gently warmed at the fire, and wiped with a dry cloth, they will better discover their Electricities' ('Pseudodoxia Epidemica,' p. 79).

"If, as shown above, the electric powers of diamond and ruby had already been observed, yet Gilbert was the first beyond question to extend the list of *electrics* beyond the class of precious stones, and his discovery that *glass*, *sulphur*, and *sealing wax* acted, when rubbed, like amber, was of capital importance. So was also his observation that electrical experiments succeed better in dry or frosty weather. Though he did not pursue the discovery into mechanical contrivances, he left the means of that extension to his followers. To Otto von Guericke we owe the application of *sulphur* to make the first electrical machine out of a revolving globe; to Sir Isaac Newton and to Hauksbee the suggestion of *glass* as affording a more mechanical construction. And both materials were discovered by Gilbert to be electrics. 'Such,' said Priestley in 1767, 'were the discoveries of our countryman Gilbert, who may justly be called the father of modern electricity, though it be true that he left his child in its very infancy.' To Priestley's quaint remark we may add that as electricity is no longer in its infancy, we who claim Gilbert as our countrymen are all the more proud to acknowledge his just claims to its paternity."

INSTITUTION OF ELECTRICAL ENGINEERS.

At the ordinary general meeting of the Institution on Dec. 10 the following were the candidates balloted for:

Members.—F. Hird, B.A., 11, Tweedy-road, Bromley; A. G. Ionides, B.A., 116, Chancery-lane, W.C.

Associate Members.—J. Addison, P.O. Box 432, Kimberley, South Africa; C. Manuel, 116, Chancery-lane, W.C.; W. J. Mitchell, Union S.S. Company, Port Chalmers, New Zealand.

Associates.—E. Butler, 171, Coatsworth-road, Gateshead; F. Dickinson, Clifton-terrace, Prescot-road, St. Helens, Lancs.; J. Z. George, Tulane-Newcomb-building, New Orleans, U.S.A.; F. C. Harding, Highstead, Brownshill-road, Torquay; W. de M. Landon, Wychwood, Poplar-grove, Sale; G. Newby, Imperial-chambers, James-street, Harrogate; C. Newton, Engine-Room Department, General Post Office, Cape Town; A. M. Niven, 74, Stradbroke-road, Southwold, Suffolk; R. Watson, Postal Telegraphs, Beaufort West, Cape Colony; E. H. W. Westwood, Knox, Schlapps, and Co., 163-169, William-street, Melbourne.

Student.—A. C. Blyth, Apartado 151, Barcelona, Spain.

PERSONAL.

The Gloucester Tramways Committee have selected Mr. E. Edwards, A.M.I.E.E., of Bradford, out of 116 applicants as general manager of the electric tramways now in course of construction. The salary will commence at £300 a year, rising by annual increments of £25 to £450.

The Sheffield Tramways Sub-Committee have selected Mr. Arthur Fearnley, of Birkenhead, to succeed Mr. A. L. C. Fell, who has been appointed manager of the London County Council tramways as general manager of the Sheffield system. The commencing salary is £700 a year.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume January to July, 1903, now ready.*

MARYLEBONE.

Unfortunately at the time of writing we cannot record the decision of the Marylebone Council as regards the imbroglio into which it has landed itself. The history of the whole case is exceedingly simple, and in its various phases have been recorded in our columns. The fundamental point is in the oft-told tale of private enterprise showing a thing to be practical and commercially successful, then municipal traders wanting to take the cream of the success to the detriment of the original pioneers. In this case the Metropolitan Electric Supply Company were the pioneers. They proved the commercial practicality of electric lighting, and the Marylebone Council determined to force the hands of the company and take over the concern. It was too good a thing to wait till the end of the period indicated by law and then take it over without paying for goodwill, but merely for the then assets. Negotiations were commenced. The company offered terms which were rejected, and, at the instigation of the Council, the matter was forced into the hands of an arbitrator. His decision was not favourable to the Council. Justice had been asked for, they got it, but they really wanted spoliation. We have no sympathy for the Marylebone Council, which went out to shear and came back shorn. Had they taken their reverse like men one could, perhaps, have spared a little sympathy, but they have not done so. Every possible suggestion has been made to repudiate what they themselves angled for and caught. It is perfectly evident that there was no counting of chickens in the earlier stages. The game was one huge matter of bluff without a single good card to play. The result will be serious enough to the ratepayers The latest development is that, owing to the financial difficulties of the Council, application was made to Mr. Justice Buckley for postponement of completion of purchase. This was granted with some demur on terms, the most important of which is that the Council pay sixty thousand pounds to the company on or before Jan. 31, 1904. Then the purchase has to be completed by Feb. 29, 1904 (Leap Year). It was pointed out that the company was in a very invidious position. It was carrying on a concern which belonged to someone else, had to expend large sums on capital account, and had an overdraft at its bankers.

The present position is this. The Council has to pay sixty thousand pounds by the end of January next, and by the end of February has to provide for an expenditure of something like two million pounds. The London County Council has refused to advance the money. The Council's bankers will advance the sixty thousand pounds, and it is proposed to promote a Bill to obtain sanction to borrow the amount required. But—and here comes the crux of the matter at this moment—such a Bill must be sanctioned at a meeting of ratepayers. Suppose such sanction is withheld—what then? The ratepayers are in revolt, and would retrace the steps taken by the Council. If the boot had been on the other foot, would they have been so anxious to repudiate? We trow not. They would have cared not one whit for the losses of unknown shareholders. In our opinion, Marylebone cannot get out of its bargain, and must do the best it can under the circumstances. The time to object was when the Council first commenced to move, or, rather, when the supply company first wanted leave to work within the borders of the borough. Why should the Metropolitan Company again negotiate? It did that long ago, and it is the fault of Marylebone, and Marylebone only, that the negotiations were not successful.

Digitized by Google

Surely we have had recently a few object lessons in the fatuousness of certain phases of municipal trading, not the least important of which is the case of Marylebone. The desire to let someone take the chestnuts out of the fire is too palpable, combined with the equal eagerness to take the chestnuts and the benefits accruing therefrom. Undoubtedly the matter is one of extreme difficulty. Lighting must savour of the nature of a monopoly, and, therefore, cannot quite be regulated as an ordinary factory production. Thus there is need for greater forethought, for greater care in acquiring information relating to every phase of the subject, and if it is a matter coming within or likely to come within the region of municipal action, casual dealing with it after the manner of Marylebone should be absolutely impossible. We have always held, and we still maintain, that pioneer workers of the class referred to should be generously dealt with in the way of money remuneration if their work is compulsorily acquired either by municipalities or governments.

THE MANCHESTER CITY ELECTRICAL ENGINEER.

The new borough electrical engineer of Manchester, appointed in succession to Mr. Metzger, who resigned, is Mr. Standen Leonard Pearce, A.M.I.C.E., M.I.Mech.E., A.M.I.E.E., whose portrait we are able to give herewith.

MR. S. LEONARD PEARCE,
The newly elected City Electrical Engineer of Manchester.

We take this opportunity of cordially endorsing the action of the Manchester City Council in placing at the head of its electrical department an engineer who is already familiar with the inner working of the undertaking, Mr. Pearce having acted as deputy chief electrical engineer to the Corporation since March, 1901. The new chief has had a varied experience, having been connected successively with Messrs. Thomas Richardson and Sons' engineering works, the British Steam Navigation Company, the Metropolitan Electric Supply Company, the British Thomson-Houston Company, and the Central London Railway. Further details of Mr. Pearce's career were given in our last issue. We wish him all success in his new and more responsible appointment.

Society of Engineers.—This society, which has just appointed Mr. David Butler Butler as president for the coming year, has awarded premiums for papers read during the past session as follows: The president's gold medal to Mr. Douglas Mackenzie for his paper on "Motor Transport for Goods," the Bessemer premium of books to Mr. Robert J. Thomas for his paper on "Road Maintenance and Administration," and a society's premium of books to Mr. Albert Gay for his paper on "Mechanical Stokers for Electricity Generating Stations."

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

STEAM TURBO GENERATING PLANTS.

SIR,—I have read with interest the correspondence following on Mr. Wilkinson's paper. As I hope to shortly have an opportunity of dealing with this question at greater length than is possible in a letter, I will not discuss in detail the accuracy of the figures quoted by your correspondents; but as more than one reference has been made to the Wallsend plant of our clients, the Newcastle-upon-Tyne Electric Supply Company, I think it well to point out that the results quoted depend upon such a variety of factors that, in the absence of fuller information, any deductions therefrom are liable to be quite misleading. As Mr. Lea points out, an attempt is being made, based upon entirely inadequate information, to compare plant working under conditions which differ almost as widely as the machines themselves.

The first of the two 2,000-kw. turbines now working at Wallsend was ordered more than three years ago, and it is sufficient indication of our opinion to say that as a result of our experience we have recently placed orders for six Parsons turbines with an aggregate output of over 11,000 kw. for our clients, the Newcastle-upon-Tyne Electric Supply Company and the Priestman Power Company.

We have also on order for another client a 500-kw. Curtis turbine, which will, we believe, be the first turbine of this type to operate in a central supply station in this country.—Yours, etc., CHARLES H. MERZ.

28, Victoria-street, S.W., Dec. 15.

SIR,—Supplementing my communication of last week, in which I referred to the fact of blades having been stripped off a large turbine in the States, I am just now in receipt of further information which shows that the difficulty is a very real one, and has not been got over. The turbine has again broken down recently from the same cause—in fact, twice. The blades were stripped, the turbine was laid off for a considerable period for the replacement of them, and then, again, after running only an hour or so the blades again stripped. When it is remembered that stripping the blades usually means the destruction of the fixed as well as the moving blades, it will be understood how serious the difficulty is.—Yours, etc.,

RECIPROCATING ENGINE.

THE DIESEL ENGINE.

SIR,—In reply to your correspondent, "E. F.," in your issue of the 11th inst., may I say that he does not appear to have understood me quite in my answer to Question 634. It is there distinctly stated that the diagram accompanying the article is only for the purpose of explaining the successive operations of the ideal Diesel engine, and is not meant to include practical modifications which experience has shown to be necessary. Whether the present external form of the engine is like that of an ordinary gas or oil engine is beside the point. The important thing is the thermodynamic cycle on which it works, the method of producing the combustion temperature, and the other points enumerated in my answer. To these points is due the high thermal efficiency not previously attained or attainable by any Otto cycle engine, and hence it is on these that stress has been laid.—Yours, etc., A. C. G. I.

CAR AXLES BREAKING.

SIR,—With respect to the article in your last issue concerning trams and tramcar wheels, the present cars at Brighton are not, in my opinion, a good type of what might have been expected from a transference of horse power to electrical traction. There is a considerable jar at the track crossings, causing heavy strains on axles, which might be lessened by raising the bed of the channel in the rails so that the wheels rested on the flanges when passing over crossings. The doorway and stairs would be more conveniently situated if at the centre instead of at both ends

Digitized by Google

of car, accommodating about eight more passengers. They would also find seats, and alight quicker. With one stairway instead of two, the driver being on top like a 'bus driver, there would be a double advantage where the trolley system is employed.—Yours, etc., S. EDWARDS.

FLATS IN COMMUTATOR.

SIR,—In reply to Mr. F. J. Hopley, the flat on the commutator may be due to three things: (1) faulty connection on commutator lug causing undue sparking; (2) defective or gritty mica between sections; and last and most likely, minute blowholes in commutator bar. Where cast bars are used, either in replacing a damaged section or throughout the whole commutator, trouble of this kind may be looked for. The only real cure is to replace faulty section by a drop forged one. If Mr. Hopley likes to try the following, however, he might cure the fault if the blowholes are only local. Take out the faulty bar, make a hole in a piece of clay twice the depth of the bar and as long as the flat, press down the bar in this till surface is level. Fill up hole (in which a few drops of oil have been poured) with lead, wrapping wet string round the lug if soldered. With a light hammer tap all over the bad piece, melt off the lead, and file up true; replace and turn true, taking off very little. This sometimes closes a blowhole.—Yours, etc.,

POLYPHASE.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

645. Describe one modern type of governor used in conjunction with steam-turbines. Give a detailed account of its method of operation and construction.—A. D.

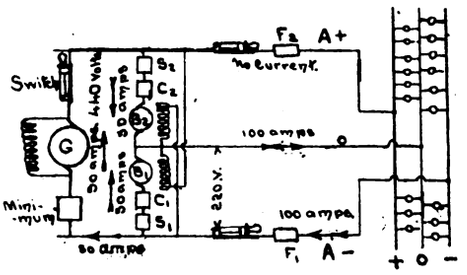
646. Give an explanation of reactance voltage in a dynamo, and a reliable method of how to calculate same. How does it affect the sparking conditions of a machine?—E. B.

[N.B.—In the answers sent in to this question there is shown a doubt as to the meaning of the same. By "doing 50 amperes out of balance" we understand the questioner to mean that the balancer can equalise the load when there is 50 amperes more on one side of the three-wire system than the other.—ED., *E. E.*]

Question No. 638. Explain and give best and safest methods of dealing with accidents which might happen as under. Supposing in a three-wire station, with voltage 440 and 220, you have a machine on the 440-volt bars, you have only one set of feeders connected +, 0, −. There is also a balancer capable of doing 50 amperes out of balance with maximum circuit breakers and starter on each outer and shunts cross-connected. If at some time you have 100 amperes each side on, and one of the outer main fuses happens to burn out, explain and give sketch as to what would happen, and the best and quickest way of righting things without the use of a battery and without damage to lamps. Also with circumstances as regards load same as above, and your machine minimum circuit breaker accidentally falls out, explain how to bring load on again with safety, your shunt resistance not being large enough to bring voltage lower than 300. —ELECTRO.

ANSWERS.

Best Answer to No. 638 (*awarded* 10*s.*).—The diagram below shows the arrangement of connections described in this question. A + and A − represent the only feeder running, and F_1 and F_2 are its fuses. If, then, as stated, F_2 burns out, all current to the positive side of mains will be cut off, and the remaining load will be 100 amperes on the negative side only. One-half of this load will, therefore, fall upon balancer B_1 to generate, and 50 amperes will be supplied to machine B_2, the positive balancer, in order to drive B_1 at the above load. This will, of course, be automatically brought about, within limits, by the crossing of the balancer shunts. What would happen then is shown on the diagram, the amount and direction of the current flowing through each machine being indicated.



For simplicity the efficiency of the balancer is taken as 100 per cent., and the amount of current necessary to run it light neglected. Thus it will be seen that the load on the main generator is 50 amperes at 440 volts, which is in effect transformed down to 100 amperes at 220 volts on the negative side. All this is assuming that the maximum circuit breakers, C_1 and C_2, of the balancers have not yet operated, which is very unlikely, as from the data given the balancer is only able to deal with 50 amperes out of balance, and therefore each machine is only capable of carrying one-half of this current, or 25 amperes. It is thus practically certain that the circuit breakers could not stand the 100 per cent. overload thrown upon them, and either one or both would operate and cut off current to the negative side of mains as well. Then, of course, the "minimum" of the main machine would fall out. The best method of proceeding in order to resume supply would be as follows: Open starting switches, S_1 and S_2, of balancers and switch off the feeder; replace the burnt-out fuse with a stronger one. Now prepare to burn out the fault on the mains which caused the original interruption. As there is no battery available for this purpose, run up and excite two or more generators, if available, and parallel them together on the unloaded 'bus bars, keeping their voltage as low as possible. Now run up the balancer, and finally switch on the feeder. It should thus be possible to burn out the fault with strengthened feeder fuses and, say, three engines running, without dangerous shock to the engines and with much smaller risk of the machines losing their field and reversing than if only one machine were used. This method is somewhat brutal, but saves time. Having in this way got rid of the fault, one machine could be left running on the normal load.

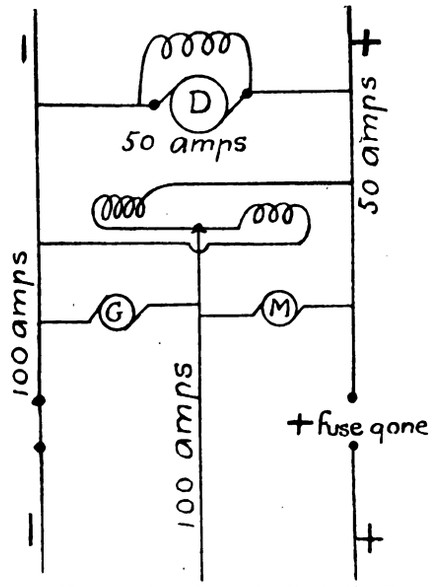
Another method of dealing with the situation would be to give up trying to resume the supply on the positive side until the fault has been removed by the mains department, and to give all attention to getting the current on to the negative side. In order to do this the balancer would have to be reinforced, and this might be done by utilising what is generally available at any central station, and that is a water resistance test tank or tub, which could be connected across the positive side in order to make an artificial load of, say, 50 amperes. One lead should be fastened to one of the studs on the positive 'bus bar, and the other on to the middle wire. It should not take more than about 20 minutes to rig up this arrangement, as even an ordinary bucket would, in the absence of a test tank, serve to dissipate the extra 50 amperes (at 220 volts) that the balancer could not deal with. The writer has had to balance a station in this way for a few days on account of the breakdown of the balancer at a time when the battery was not available.

In the second case should the main machine "minimum" accidentally fall out the load could be put on again as follows: switch off balancer and feeder, now, as described above, parallel two or three engines together on the unloaded bars, next run up balancer, and last switch on the feeder; the load would now, as before, be divided amongst the machines. In this case again the water resistance

Digitized by Google

could be utilised if the spare plant were not available, as it could be connected across the bolts of the machine main switch, and the load thus brought on gradually through the resistance; when the full load was approached the switch could be put in, thus cutting out the resistance, which could then be disconnected.—D. J.

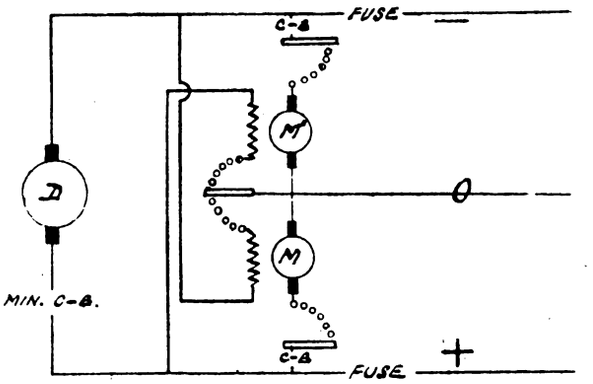
Answer to No. 638 (*awarded* 7*s.* 6*d.*).—With regard to the first part of this question, in the event of the main fuse on the outer of the set of feeders burning out we have the following results: Half the load on the generator is suddenly thrown off, causing a sudden rise of pressure across its terminals, all the lights on the side on which the fuse blows being put out. The generator is now doing 50 amperes, and we have 100 amperes going through the middle wire to supply the other side. The balancer is doing its full duty, dealing with the 50 amperes out of balance. As shown in rough sketch, it is taking 50 amperes from the + side "for motoring," and on the − side is "generating" 50 amperes, which with the 50 amperes from the main circuit makes up the total load on the − side of 100 amperes. The occurrence would be dealt with in the following way: Resistance put into the shunt of generator to bring rise of voltage down, then if there is a regulating resistance between the middle-wire connections of balancer shunts this would be adjusted so that the field of the − balancer was fully excited, leaving all the resistance in that of the + balancer, now "motoring." The fuse on the + outer of feeders can now be replaced (provided, of course, that it has simply burnt out, and that is not case of a "short" still on), and the generator and balancer resistances again adjusted. In this way the normal conditions would again be reached, and with a good balancer the lamps should not be badly over-run.



D, Generator giving 50 amperes to main circuit; M, Positive Balancer motoring 50 amperes; G, Negative Balancer generating 50 amperes.

With regard to the second part of the question—*i.e.*, in the event of the minimum circuit breaker falling out and throwing the load off the generator, etc.—the speed of the engine would have to be reduced as much as possible, the balancer being, of course, left on, and slowing down with the engine. In this way, with the shunt resistance all in, the voltage can be steadily reduced below the 300 mentioned. The minimum circuit breaker should then be put in, and the engine gradually run up to full speed, the balancer speed increasing also with the voltage, and the load being safely brought on again.—DOUGLAS KELLEWAY.

Answer to No. 638 (*awarded* 5*s.*).—Premising that the connections are as shown as in sketch, suppose first that with 100 amperes on each side one of the main fuses, say the one on the positive side, burns out. M will then, owing to its weakened field and the greater potential across its brush, tend to run as a motor, and M^1 become a generator. There will not be 100 amperes to be delivered by the middle wire, as the current will be lowered in proportion to the voltage drop between the middle and negative conductors. With everything in order, therefore, M^1 should give an approximate 50 amperes, and the other approximate 50 amperes pass through M from the positive terminal of main dynamo, D. To replace burnt-out fuse, cut down volts on D to 300; the current flowing in its armature will then be about 40 amperes.



Open the main circuit, open starting resistances of M and M^1, and replace fuse. D should now have its circuit closed, M and M^1 be put to line, and voltage brought up to normal. If minimum circuit breaker of D fall off, starting switches of M and M^1 should be opened, voltage of D lowered, and the circuit breaker replaced. M and M^1 are then started and volts readjusted. There will probably be no occasion to alter resistance between the shunt windings, as presumably both sides would be in balance at time of accident.—M. M.

THE SLOW REGISTRATION OF RAPID PHENOMENA BY STROBOGRAPHIC METHODS.*

The "Ondographe" and the "Puissancegraphe" (Wave Recorder and Power Recorder).

BY E. HOSPITALIER, FOREIGN MEMBER.

As one of the oldest of the French members of the Institution of Electrical Engineers, and as one who has always followed its proceedings with the greatest interest, the author regards it as a great honour to be permitted to place before the Institution an apparatus for which he begs the indulgence and consideration of his audience, if, by reason of its industrial and practical character, it should appear to them at all out of keeping with the scientific character of the subjects which are commonly dealt with at their meetings. The object of the "ondographe," and of other instruments derived from it, is to register within a reasonably long period of time (of the order of from 15 to 60 seconds) a periodic phenomenon of so rapid a nature that the period may be as short as one-thousandth of a second, or even less. Before entering, however, upon the description of the apparatus, it will be necessary to refer to certain general considerations. The observation of a rapidly variable phenomenon may be effected with the aid of apparatus based upon two very different principles—viz., direct observation and indirect observation.

Direct Observation.—The apparatus to be used for observation or registration should be capable of following the phenomenon instantaneously and without affecting it in any way. This result may be attained by either of two methods. That most commonly employed consists in designing the instrument so that it has a small moment of inertia, a very short natural period of oscillation, compared with that of the phenomenon to be recorded, and a degree of damping as nearly as possible critical—that is to say, it is so damped that the apparatus, when disturbed from its position of equilibrium, tends to return to that position in the shortest possible time and without over-shooting. The second method, which is at present represented only by Mr. Abraham's rheograph used in studying the characteristics of variable currents, involves the use of an observing instrument in which the moment of inertia is high and the natural period of oscillation is much greater than that of the phenomenon to be observed. Under these conditions the instrument would indicate something different from the phenomenon which it is wished to observe. However, it is not submitted to the action of the phenomenon itself, but to that of one more complex, which has been previously regulated in such a way that the disturbing effects due to inertia and to damping of the oscillat-

* Paper read before the Institution of Electrical Engineers, Dec. 10

Digitized by Google

ing system are compensated. In this way the same result is obtained as with an instrument without inertia; but these compensations at present only appear to be possible for the observation and measurement of electric currents.

Indirect Observation.—Indirect observation, based upon stroboscopic principles, is effected by reproducing the phenomenon with a much longer period, obtaining the record of the whole of its phases by taking them successively from a large number of periods. The period of oscillation peculiar to the apparatus may in this case be very long as compared with that of the phenomenon observed, provided that the duration of the total number of periods from which the different phases are collected is itself very great relatively to that of the oscillation peculiar to the recording instrument.

1. Direct Methods.

In order that a recording apparatus may follow a given phenomenon with precision, it must satisfy the following conditions: (1) the period of of oscillation must be very short as compared with that of the phenomenon to be studied; (2) the damping must be approximately aperiodic; (3) disturbing causes due to the apparatus must be as small as possible; and (4) it must be sufficiently sensitive. The first condition is realised in practice when the period of oscillation peculiar to the system of the measuring instrument is about 50 times as short as that of the phenomenon to be observed. This condition is readily satisfied when the frequency of the phenomenon under examination does not exceed from six to eight per second. Beyond 500 periods per minute, the disturbance caused by the inertia of the moving parts, and the excessive or insufficient damping, render the indications illusory, unless special arrangements are made. The theoretical study of the conditions to be fulfilled has led to the development of instruments such as the oscillograph of M. Blondel and that of Mr. Duddell, which the members of the Institution have had the opportunity of seeing in this room.

2. Stroboscopic or Indirect Methods.

Notwithstanding the elegance of the direct methods, and the results which have already been attained with instruments based upon them, the author is of opinion that the industrial future is reserved to the indirect methods, which have a wider field of application, and which permit of the direct recording of the phenomenon to be studied upon a strip of paper, in a way that is not possible with the direct methods, in which recourse is always had to photography. In order to understand the principles of the stroboscope as applied to the observation and recording of periodic and rapidly varying phenomena, the most simple of all the periodic movements may be considered—namely, that of uniform rotation. At the end of every revolution the rotating system attains the same relative position that is occupied one complete turn earlier. Suppose now that the system is illuminated for a very brief instant once in each revolution at the moment at which it passes a certain position, which is regarded as the initial position. The rotating system will then appear at rest. If, now, the periodic illumination be slightly retarded, so that the successive flashes follow one another at an interval of time a little longer than the period of the revolution itself, the system will be illuminated in its various phases in turn, and will appear to revolve slowly in the sense of its actual rotation. If, on the contrary, the flashes follow at shorter intervals, the system will appear to be turning in a sense inverse to that of its real rotation, since at every revolution it will be illuminated an instant before it attains the same position as on the preceding revolution. In this way the apparent velocity of rotation will have been reduced in a proportion which depends only on the acceleration or the retardation of the successive illuminations of the system. The simplest means of obtaining these successive flashes consists in using a disc pierced with a slit as a shutter in front of a projector. The same result may be obtained by means of the sparks caused by interrupting the current through an inductance, or with alternate-current arcs, etc., but the sharpest effects are obtained with the revolving stroboscopic disc.

In order to obtain a variable difference in the periods or slip, it is possible to use an electric motor, of which the speed is capable of variation—or a synchronous motor if the system is driven by a synchronous machine—which determines the measure of the slip, or a train of wheels, as in the ondograph, or (the most rational of all) a differential gearing, of which one of the axes is controlled by the system to be studied, whilst the other actuates the stroboscopic disc, and the crown containing the intermediate wheels between them receives from an outside source a more or less rapid movement of rotation which defines the slip. This disposition offers the great advantage of allowing the phenomenon to be apparently stopped in any specially interesting position. The stroboscopic method is the basis of a large number of instruments, which may be classed in two groups: (A) stroboscopes, or apparatus used for observations; (B) strobographs, or recording apparatus. It is proposed to limit this paper to the study of instruments of which the applications are directly or indirectly connected with electricity.

A. Stroboscopes.

Stroboscopes, of which the number is infinite, do not, properly speaking, constitute apparatus, but rather experimental arrangements which are susceptible of modification depending upon the material at the disposal of the observer, and upon the research that he has in view. By way of example, reference will be made to those which the author has used for the examination of alternate-current arcs and of machinery in motion.

The Arcoscope.—A very simple experimental arrangement has been designated by this name (which is at once French and Greek), an arrangement intended to facilitate the examination of the variation in the luminosity of an alternate-current arc during a single period—variations which it is impossible to observe directly because of their great frequency. It consists, in principle, of a small asynchronous single-phase alternate-current motor, having on its axis an opaque disc provided with narrow slits placed at regular intervals, the number of the slits being equal to the number of pairs of poles of the motor. Thus, for a motor with four poles, the disc would have two slits, placed one at end of the same diameter. The motor is driven by alternate current taken from the same source as that traversing the arc under examination. The disc, which is rotated by the motor at quasi-asynchronism, is placed in the path of the luminous rays emitted by the arc, which latter is projected by a lens upon a screen. The image of the arc is thus allowed to fall on the screen for one instant during each period, and in consequence of the slight slip of the motor when running light, the phenomena of the arc may be observed during a complete period, and this period may thus be prolonged to as much as from 10 to 15 seconds. By applying a braking action to the motor the slip is increased, and the apparent duration of the oscillation of the light of the arc is reduced. It is possible to observe the arc directly through the slits in the disc, but the result is less clear than when a projection is used and the image of the arc is magnified. If the same disc be made to carry a series of sectors, alternately white and black, the number of each kind being equal to that of the poles of the motor, and if it be illuminated by an arc or incandescent lamp served by the same current as is the motor, the slip of the motor may be observed and directly measured by observing and measuring the apparent inverse rotation of the disc mounted on its shaft. In this way it is in some degree possible to analyse the light of the arc, and to judge the influence of the form of the current curves, of the nature and quality of the carbons, of the frequency, the conditions of regulation, etc. It is also practicable to cinematograph the phenomenon in order to be able to study it at leisure. This can be done by controlling the cinematograph by means of an asynchronous motor and photographing the arc, either directly or after projecting it upon a screen.

Stroboscopic Transmission Dynamometer.—If a driving shaft, A, actuates a working shaft, B, through the medium of a spring coupling between the two shafts, the product of the torsional couple or torque transmitted by this spring, multiplied by the angular velocity, is equal to the power transmitted by the shaft A to the shaft B. A large number of arrangements have been devised to determine this torque, which generally shows itself in practice by a relative angular displacement of the two shafts proportional to the torque. A simple means of reading this consists in mounting a disc on each of the shafts, and in placing the rims of the two discs close together and marking on them graduations proportional to the couple exerted in each or the relative positions of the discs. When the system is in motion, the relative displacement of the two shafts can be read off on the graduations, just as if the discs were stationary, by illuminating the system once in each revolution at the same instant in each period. For this purpose the stroboscopic eyeglass can be used with advantage.

Stroboscopic Eyeglass.—A small electric motor, driven by two accumulators, actuates a disc pierced with radial slits. The system in rotation is viewed through these slits with one eye, the other remaining closed. With the aid of a rheostat the disc may be caused to revolve at various speeds, so regulated that the system, illuminated permanently from an external source of light, appears to be either stationary or revolving very slowly. The stroboscopic eyeglass, so arranged, when brought to synchronous speed, permits the graduation of the above-described dynamometer to be observed and read with ease. If it revolves with a certain amount of retardation, it allows of the observation of rapid phenomena as readily as if they were produced at a slow speed which can be regulated at will. All the phases of an explosion engine may, for example, be thus observed: the lifting of the valves, the contact and the ensuing vibration of the ignition cam, the formation of the stitch in a sewing machine, the starting of a part having an independent movement, etc.

Differential Stroboscope.—For the study of thermal engines, MM. Malicet and Blin have constructed for the author a special differential stroboscope in which the motor is illuminated only once in every two revolutions. This result is obtained by providing the stroboscopic disc with only one slit and mounting the

Digitized by Google

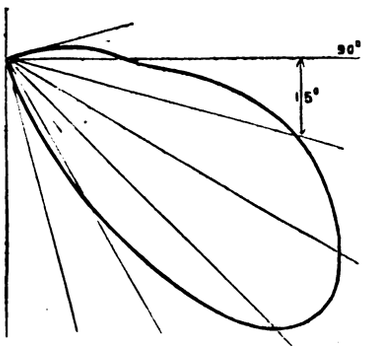
disc on the crown of the differential gearing. One of the shafts of the gearing is connected by a flexible shaft to the motor engine under examination, and the other shaft, in order to produce the stroboscopic effect, may be rotated slowly by means of an endless screw controlled by a small handle turned by hand. The apparent velocity of rotation of the engine is varied by turning the handle more or less rapidly. On stopping the handle the apparent movement is also arrested. Examples could easily be multiplied, but those which have been given suffice to show the important part that can be played by stroboscopic methods—confined, so far, to the laboratory of the physicist—in taking their places in the test-rooms of the great mechanical and electrical industries.

(To be continued.)

TRADE NOTICES AND NOVELTIES.

General Electric Company's British-Made Carbons.

It is only within the last two years or so that the manufacture of arc lamp carbons in this country has been brought to a successful commercial stage. True, many attempts have been made to arrest the large imports of carbons from the Continent, by producing a home-made article of equal merit, but until the General Electric Company entered the field no really effective opposition had been offered to these imports. The company deserve every encouragement, therefore, in the plucky attempt which they are making to reclaim an industry which, though first introduced in this country many years ago, has been allowed to slip into the hands of Continental manufacturers. The difficulty has been to produce an article in England capable of competing successfully with the carbons turned out by foreign firms. This the General Electric Company have succeed d in doing, and they are to-day producing arc lamp carbons at their Witton Works which, both in point of quality and general efficiency, are claimed to be at least the equal of any of the leading Continental makers.



PHOTOMETRIC TEST OF
THE BIRMINGHAM CARBON WORKS.
ENGLISH MADE CARBONS.
18 m/m Cored Positive
12 m/m Solid Negative.
Current 10 Amp.
Arc E.M.F. 42 Volts.
SCALE
0 100 300 candles.

Tests have been carried out quite recently, and we are indebted to the General Electric Company for a report of the same, which contains some striking figures in proof of the high state of efficiency and economy to which the English-made carbon has been brought. The tests in question were carried out on five 10-ampere "Angold" arc lamps in series, fitted with the firm's "Apostle" carbons, of which the following were the dimensions: 18mm. by 12in. long cored, 18mm. by 12in. long solid, the weight of a pair being 162 grm. The average line pressure was 238 volts, and allowing a drop of 23 volts in the steadying resistance, the average pressure across the lamps was 215 volts, or 43 volts per lamp. An average current of 10 amperes was used. The tests lasted 20½ hours, and the average rate of consumption of the carbons per hour was ·506in., or 1·282cm., for the cored and ·451in., or 1·145cm., for the solid. The first lamp gave an ash residue of 3·7 grm., the second the same, the third was open, the fourth gave 3·2 grm., and the fifth 4 grm. Thus the average ash of the four lamps with globes was only 3·65 grm., or 2·25 per cent. The total volume of ash from the four lamps was 22·6 cubic centimetres, and the rate of the volume of the ash to the weight of the ash equally $\frac{1·54}{1}$. The carbons started up without flaring, with full pressure across the five lamps, and normal resistance in circuit. They continued to burn absolutely steady during the whole time of testing, while the formation of the arc was normal. The above satisfactory results, it will be observed, were obtained under ordinary working conditions, and are in no way exceptional for "Apostle" carbons.

We may also give the results of a highly successful photometric test of the company's carbons carried out by the Electric Standardising and Training Institute. The sizes of the carbons used were the same as in the tests above described. The voltage across the arc was maintained at 42 volts to a current consumption of 10 amperes. The test showed that the maximum light ray occurred at an angle of about 38deg. from the horizontal, when it was of the value of 1,820 c.p. At 50deg. the candle-power was still 1,500, and the same at 20deg.; thus over an angle of 30deg. there was only a fall of 320 candles, or 16 per cent. of the maximum candle-power obtained. If we take the results of this test and apply them to the figures obtained in the previous tests, we find that the consumption of current expressed in watts per maximum candle-power is only 0·24—a remarkably low record.

Fuses, etc.

From Messrs. Ernest F. Moy, Limited, Greenland-place, Camden Town, London, N.W., we have a sheet dealing with their supply companies' fuses, type No. 76, for pressures up to 250 volts. An illustration is given of a single-pole fuse box. In this box the terminals are fitted with sweating sockets, which can be readily removed for the purpose of connecting up. The base is of highly vitrified porcelain with stout raised sides, which project well above the fuse strip. The box is stove enamelled, and fitted with the usual inspection window in the cover, which latter is hinged to the box and fastened by a sealing bolt. Three sizes are made—namely, for 25, 50, and 100 amperes. The firm's stage plug, type No. 283, is described on another sheet.

Cables.

From Messrs. Johnson and Phillips, Old Charlton, Kent, we have received a price-list dealing with their L.T. "Mauilla" paper-insulated lead-covered, lead-covered and armoured, and twin house-wire cables. On the back of this list is an illustration of a large shipment of the firm's cables for Kimberley.

An Artistic Production.

We have pleasure in acknowledging the receipt of a handsome calendar from the United States Metallic Packing Company, Limited, Soho Works, Bradford. The feature of this gift is a charming art bas-relief representing "Ceres," Goddess of Harvest. So unique a combination of utility with artistic beauty will, no doubt, be in great demand.

Flexible Tubing.

Messrs. John Lawman and Co., 143, New Kent-road, London, S.E., have sent us some particulars and a sample of the flexible tubing of special manufacture which they supply for the protection of electric cables. This tubing is largely used for covering portable cables exposed to the liability of external damage, serving as a mechanical protection without impairing the flexibility of the cables. The various sizes and weights of this tubing can be supplied either zinc, brass, copper, or nickel plated as required.

Cranes.

We have received a copy of a new catalogue illustrating some of the cranes constructed and erected by Messrs. Thomas Broadbent and Sons, Limited, Central Ironworks, Huddersfield. The firm have standardised two types of electrically-driven overhead cranes—namely, the multimotor and the monomotor types. Extended descriptions are not included in the catalogue, the illustrations being largely left to speak for themselves, but special features are, of course, mentioned. One of these consists of an automatic mechanical brake fitted to the hoisting motion of the firm's three-motor type of crane. The arrangement is such that the brake pressure is applied by the load, the friction on the pulley being always in direct proportion to the load on the hook. The brake pulley itself is on the free wheel principle, and only revolves when the load is being lowered, so that in hoisting there is a total absence of brake friction. In addition to the above an electric brake is fitted to the armature of the hoisting motor, operated by a solenoid connected in such a manner that, should the supply of current be interrupted through any cause, the brake will immediately apply itself and prevent the running down of the load. The longitudinal and cross-travelling motions are also fitted with electric brakes when the speeds are abnormally high. Evidently both the mechanical and electrical details of these cranes have received very careful attention.

BARKING ELECTRICITY ACCOUNTS.

FORTHCOMING EVENTS

Friday, Dec. 18.

North-East Coast Institution.—At 7.30 p.m., general meeting at Newcastle. Discussion on Mr. Max Wurl's paper on "Technical Education in Germany." Paper: "Notes on the Construction of Stability Cross Curves from Balanced Paper Sections," by Mr. John H. Heck.

Institution of Mechanical Engineers.—At 8 p.m., ordinary meeting. Papers: "An Enquiry into the Working of Various Water Softeners," by Messrs. C. E. Stormeyer and W. B. Baron.

Electro-Harmonic Society.—At 8 p.m., in the King's Hall, Holborn Restaurant, smoking concert.

Institution of Civil Engineers (Students' Section).—At 8 p.m., ordinary meeting. Papers: "The Action of the Sea upon the Foreshore," by Mr. C. B. Case; "The Causes of the Loss of Beaches," by Mr. F. W. Cable.

Saturday, Dec. 19.

Junior Institution of Engineers.—At 3 p.m., visit to the electricity works of the Walthamstow Urban District Council. Train leaves Liverpool-street at 2.23 p.m.

Tuesday, Dec. 22.

Institution of Civil Engineers.—At 8 p.m., ordinary meeting. Paper: "On the Resistance of Plane Surfaces in a Uniform Current of Air," by Mr. T. E. Stanton, D.Sc.

NEW COMMITTEES.

Aston.—*Electricity*—Alderman Gittings; Councillors A. E. Godrich, C. Barnard, T. P. Bird, J. E. Berry, F. S. Tomey; and the Mayor (*ex officio*).

Hereford.—*Electricity*—Mr. W. Hewitt, chairman; Aldermen H. C. Beddoe (mayor), T. Llanwarne, and T. W. Clarke; Councillors S. Bye-son, W. C. Gethen, E. W. Langford, and S. H. Prosser.

LONDON TRAFFIC ENQUIRY.

The Royal Commission on London Locomotion sat at the Westminster Palace Hotel on Thursday and Friday last week, the chairman, Sir David Barbour, presiding.

Mr. R. F. Whur, vice-chairman of the Works Committee of the Paddington Borough Council gave evidence as to the statutory powers possessed by certain public companies to break up streets on serving notice on the borough council, and the disastrous effects on the surface of the roadways, and suggested that they should be prohibited excepting in cases of great urgency from making openings during December, January, and February, and compelled to lay new mains and execute necessary repairs, save only those of great urgency, within a period of three months before a carriageway was to be repaired, and only subsequently to notices given by the borough council, or at such periods as might be fixed. He considered that the introduction of a central authority having powers in reference to the breaking up of roads would cause friction between it and the local authorities, involve a multiplication of officers, and generally be to the public disadvantage. The extension of underground railways or shallow tramways in accordance only with a scheme embracing and providing for the needs of the whole of London would considerably mitigate the existing difficulties of locomotion in London, and in illustration of that he pointed to the relief of the traffic in Uxbridge-road since the opening of the Central London Railway. He objected to the removal of the existing right of a borough council under the Tramways Act and the Standing Orders of Parliament to veto a tramway scheme passing through their district which would be inimical to the best interests of the ratepayers. Where it was essential for the proper construction of a tramway that street widenings should be carried out, the whole costs attached to the construction of the tramways and the execution of the street widenings should be borne by the tramway authority, and not shared between that authority and the local or road authority. The fixing of point stations or stopping places for omnibuses would greatly relieve traffic, as it would enable the police to prevent the stopping of all omnibuses at other than the authorised points, as was the case with electric trams.

Mr. W. N. Blair, borough engineer and surveyor for St. Pancras, stated that it was of the greatest urgency that the widening of Hampstead-road, authorised by the Act of last year, should be carried out; but the County Council had repeatedly sought to make it a condition that, before they proceeded with the widening, the St. Pancras Council should give consent to the continuation of the tramways down Tottenham Court-road, although Parliament had expressly declined to recognise any such compact. The Borough Council had expressed their willingness to reconsider the proposal to lay tramways in Tottenham Court-road if proper widening was undertaken, and also that the tramway should not terminate at Oxford-street but continue to Charing Cross; but having regard to the fact that the Charing Cross, Euston, and Hampstead Tube Railway was now in course of construction on this particular line of road, it was doubtful, in the opinion of the Council, whether any necessity to extend the tramway was likely to exist on the completion of the tube railway.

Mr. W. C. Leete, town clerk of Kensington, having given evidence,

Mr. Henry C. Jones, town clerk of Holborn, stated that the Council attached the greatest possible importance to the tube railways already sanctioned by Parliament, and had supported the proposals of the Charing Cross, Euston, and Hampstead Railway Company to make a connection at the junction of New Oxford-street with Tottenham Court-road and Charing Cross-road with the Central London Railway. They were now carrying out, at the expense of the railway, very considerable works with a view of enabling that connection to be made. A scheme for an interchange station between the Great Northern, Piccadilly, and Brompton Railway Company and the Central London at High Holborn was also supported by the Council. His Council cordially supported shallow underground tramways, but surface tramways should not exist in the central parts of London. Continuing, the witness said that in Gray's-inn road and Theobalds-road the omnibuses carried on a recent day 39,843 passengers, as against 28,278 by the trams, and did not cause nearly so much congestion, by reason of their mobility. As to the right of veto at present enjoyed by road authorities with regard to the introduction of Tramway Bills, his Council were strongly of opinion that no case had been made out for interfering with the rights given them by the Tramways Act and by the Standing Orders of both Houses of Parliament. With regard to the establishment of some authority or tribunal to which all schemes of railway or tramway construction should be referred, his Borough Council suggested that the functions of such a tribunal should be judicial, that they should be absolutely independent, and that they should be appointed for a period. He suggested a tribunal somewhat on the lines of the tribunal of appeal constituted by the London Building Act, 1894, or the Court of Arbitration under the London Water Act, 1902. He did not think that either county councils or borough councils ought to be represented upon that body.

Mr. H. Edwards, borough engineer of Lambeth, said his Council saw no reason why the London County Council, in their tramway operations, should be dealt with in any other manner than a private promoter. With reference to the use of the carriageway generally, the electrification of the tramways had had a marked effect upon vehicular traffic. The old rate of progress had quite changed, and all other traffic had been thrown completely on to the sides of the carriageway, for the upkeep and maintenance of which the local authority was responsible, and with the prospect of express trams this monopoly of the greater portion of the road would be much increased.

Mr. T. W. E. Higgens, borough surveyor of Chelsea, said that his Council, in common with some other borough councils, had grievances against the London County Council. They had been asking for a long time for contributions towards widening King's-road. The Improvements

Digitized by Google

Committee of the London County Council recommended that the London County Council should bear two-thirds of the cost of widening the street, but when the matter came before the London County Council last year an amendment was moved recommending that only half the cost be borne by the London County Council unless the Chelsea Council would agree to tramways being laid down the centre of King's-road, and the matter was still delayed. His Council considered that the London County Council would not give adequate contributions towards street widening unless tramways were laid in the streets; they also felt that the London County Council had no settled policy for carrying out street widenings. If a generous offer was made by a local authority to bear the cost of an improvement, the London County Council would try and squeeze a larger contribution out of them, whereas in cases where the local authority would give nothing the London County Council often stepped in and carried out improvements almost entirely at their own cost. Their vexatious rule that they would not contribute to any improvement unless they had been first consulted led to injustice and delay.

The Commission adjourned.

LEGAL INTELLIGENCE.

FERRANTI LIMITED.

In the High Court of Justice on Tuesday Mr. Justice Buckley, sitting for the disposal of companies' business, had before him an application on behalf of a creditor of this company asking for the production of certain documents referred to in an affidavit filed on a petition for liquidation.

Mr. Buckmaster, K.C., for the petitioner, said he was a creditor for dishonoured bills, and he had presented a petition for the winding up of the company. The answer put in to that petition consisted chiefly of an affidavit by certain receivers who had been appointed in a debenture-holders' action. They had been appointed on Sept. 9, 1903, and the main ground of their objection as disclosed in their affidavit was the allegation that certain contracts, of which the company had the benefit, contained clauses which would cause the contracts to be forfeited in the event of a winding-up order being made. On that affidavit being served it was suggested that the creditors should call a meeting to consider what should be done. The petition accordingly stood over for a fortnight till the creditors' meeting was held. At that meeting a committee was appointed, one of the members of that committee being the petitioning creditor. On Dec. 1 his Lordship allowed a further adjournment until the first petition day of next sitting, in order to see if this committee would recommend any course. Several applications had been made to the solicitors for the defendants, who had sworn the affidavit, asking for liberty to inspect the documents, but the petitioning creditor had been unable to obtain inspection of them.

Mr. Vernon, for the receivers and managers, said they were really no parties to these proceedings at all. He submitted that what they had done was perfectly right in the circumstances. They were willing to give any reasonable information, but they considered it undesirable and detrimental to the interests of the company that such contracts should be produced. They were further instructed that the company could not conduct its business if these contracts were taken from the works at Manchester. If copies were made it would lead to very considerable expense, and would be an oppressive proceeding.

Mr. Buckmaster said he wished to see the forfeiture clauses.

Mr. Vernon said he was perfectly willing to give verified copies of these as well as the dates of the contracts. The reason the receivers and managers were so cautious was because Mr. Ferranti and Mr. Anderson had specially warned them that it would be detrimental to the company to produce any contracts relating to the works. There was danger of these becoming known to competitors in the trade.

Mr. Buckmaster said that the petitioner was Mr. Estler, and the petition was in respect of goods supplied. He did not carry on business in competition with the company, nor was he in a position to undertake the work.

His Lordship said it was perfectly reasonable that the contracts should not be produced. The receivers and managers must, however, give copies of the forfeiture clauses, and so far as possible dates fixed for the completion of these contracts. The costs would be costs in the petition.

TRAMWAY COMPETITION IN VIENNA.

In the Chancery Division on Friday Mr. Justice Farwell had the matter of Richmond *v.* the Vienna General Omnibus Company, Limited, before him on a motion by the plaintiff, a debenture holder to the amount of £2,000 out of £50,000, for the appointment of a receiver and manager of the company's property on the ground that there was default in payment of interest, and the notice of motion asked that Mr. Neville, who had acted as auditor of the company since its formation, should be appointed. The company had made losses, it was said, for each of the three last half-years of £1,616, £2,500, and some £3,000.

Mr. Wilkinson, on behalf of the company and bearer debenture holders to the amount of £27,800, opposed the motion. He said that if the order were made it would have the effect of sinking the ship. The company was struggling against the electric tramway system now being introduced into Vienna, but by a deviation of route where the electric system did not prevail the company hoped to improve its position.

After hearing **Mr. Austen Cartmell** for the trustees, **His Lordship** made the order asked for, the managers of the company not to act beyond six months without the leave of the Judge in Chamber.

In another motion by **Mr. Upjohn, K.C.**, against the company, it was agreed that no order should be made save that the costs should be reserved.

ST. MARYLEBONE ELECTRIC LIGHT.

On Friday last the action of the Metropolitan Electric Supply Company, Limited, *v.* the Mayor, Aldermen, and Councillors of St. Marylebone came before Mr. Justice Buckley in the High Court.

Mr. Buckmaster, K.C., moved on behalf of the defendants that the time which the Court fixed for the completion of the purchase by the defendants of the plaintiffs' undertaking might be extended. The Corporation became bound to buy the undertaking of the plaintiffs in their district. The purchase price had been fixed by arbitration at £1,212,000. An action was brought, and the Court ordered the specific performance of the contract. It was impossible to raise the money by loan, and a rate would mean, apart from other rates, one of 20*s.* in the pound. In order to get out of the difficulty the Council had decided to appeal to Parliament, but under the Act they must first obtain the opinion of the ratepayers. The earliest date at which that could be done was Jan. 28, 1904, and the latest Feb. 18, while on Dec. 31, 1903, they were bound by his Lordship's order to complete the purchase and pay money which they had not got, and could not by any possibility obtain. They, therefore, asked for an extension of time for them to see if they could secure relief from Parliament to enable them to carry out the bargain.

Mr. Cripps, K.C., for the company, pointed out that they had nothing to do with the means of raising the money, but they dissented from what was said about the difficulty of raising it. If the proposed Bill were accepted by the ratepayers, the company were prepared on that basis to give all proper indulgence to the Borough Council, but on terms. In the other alternative, which was not an improbable one, of the ratepayers rejecting the idea, the method of procedure would be for the company to enforce their rights by applying for a mandamus to have the rate enforced.

Mr. Justice Buckley: The crux of the case is that the Borough Council have unfortunately involved themselves in enormous liability which they do not find themselves in a position to discharge. They ought to have thought of that before coming under the statute.

Mr. Cripps said they could not play fast and loose with the company. He did not think any other municipality in the country had ever taken up such an attitude to escape from a liability, which it had undertaken on its own motion, because the arbitrator had not decided just as it wished.

Mr. Justice Buckley: It is for them to find the money, but it is for me to see that they have a reasonable opportunity of complying with an obligation which, in my view, they have been very foolish to place themselves under. It is a complete satire on municipal trading. The unfortunate ratepayer finds himself in this position through no fault of his own, but by that of his representatives.

Mr. Buckmaster repudiated any desire or wish on the part of the Council to escape from the bargain.

Mr. Justice Buckley, in giving judgment, said that the Council seemed to have gone with a light heart and obtained powers which compelled them to buy and the company to sell. To comply with that they wanted a million and a quarter, and, of course, they had not got it. They endeavoured to get sanction to borrow and failed. To obtain the whole capital sum by a rate would mean such a very heavy burden on the ratepayers that his Lordship was not surprised that the Council were afraid. Now they were in it, it was for the Council to resolve their own difficulties. The position was complicated by the fact that the undertaking required perpetual addition and extension, and capital expenditure had to be increased. As matters stood at present the company were the custodians of somebody else's undertaking, for which somebody else would not pay. If the ratepayers did not approve the proposed Bill, the situation would become more acute. His Lordship was of opinion that there should be an extension of the time of completion of the purchase till Feb. 29, but only on certain terms. The company said it was not reasonable to expect them to raise more capital, and they had borrowed from their bankers at 4½ per cent., and they said that that interest and the money expended for further capital expenditure should be paid by the Council. There was great justification in that argument, and the borough must pay £60,000 and 4½ per cent. on £7,250. The evidence was that that would require a rate of something like 9d. in the £. There would be the further term that there should be added to the purchase money such other expenditure as the plaintiffs should make in respect of reasonable and proper expenditure on capital account.

Order accordingly.

GEO. F. MILNES AND CO.

In the Chancery Division on Tuesday before Mr. Justice Farwell, Mr. R. J. Parker, in a debenture holders' action of the Bank of Liverpool, Limited, *v.* George F. Milnes and Co., moved for judgment in default of defence. The bank holds a third debenture and the whole series of the second debentures, while the Law Guarantee and Trust Society was trustee for first and second debentures. An interim order has been made for the appointment of a receiver and manager, and counsel asked that this appointment should be continued in chambers. It was one of those cases in which, no doubt, everybody would be paid, and the bank was meanwhile advancing the money.

His Lordship gave judgment on the minutes submitted, which were in the usual form, with a declaration as to the bank's charge, and the customary enquiries.

WEST WALES TELEPHONES.

At Haverfordwest County Court on Tuesday, Judge Bishop heard a number of cases in which the National Telephone Company were the

Digitized by Google

plaintiffs and several inhabitants of Haverfordwest were the defendants, arising out of claims for rental of telephones alleged to be due. The amounts sued for were from £17 to £24 for three years at £8 a year

The case for defendants was that when they signed the contracts they did so on the understanding that a Pembrokeshire exchange area was to be established, which would include the most important towns in the county. Such an exchange area had not been provided, and they contended that the telephones had not served the purposes for which they required them. Each defendant had paid a small amount into court.

The plaintiffs contended there was no promise, but it was stated by the company's representative that they were about to open out in the county if subscribers could be obtained. The company could not guarantee that there would be subscribers.

His Honour held that the evidence showed that defendants were given to understand there would be communication with other towns in the county, but the promise had not been fulfilled. Therefore, when defendants got their telephones they found they were no use. He, however, reserved judgment.

ALLEGED THEFT OF ELECTRICITY.

Walter Lawrence, stated to be an electrical engineer, was charged on remand, at Bow-street Police Court on Thursday last week, with stealing 10s. worth of electricity at his rooms in the Strand. The facts of the case were given in our last issue.

The **Magistrate** said that, as a warning to others, there would be a fine of £5.

COMPANIES' MEETINGS AND REPORTS.

NERNST ELECTRIC LIGHT.

The ordinary general meeting of the shareholders in this Company was held on Tuesday at the Westminster Palace Hotel, S.W., Mr. Bernard M. Drake presiding.

The **Chairman** said the balance-sheet showed that they had made a net profit during the past year. He regretted that Mr. Hugo Hirst had found that his other engagements prevented his continuing to occupy a seat on the Board. Mr. Hirst had, however, kindly offered the benefit of his advice on all questions arising out of the policy which had been adopted during his term of office. Turning to the balance-sheet, they had made a net profit of £3,926. 1s. 11d. for the year, as against a debit of £3.157. 9s. 7d. for the previous year. The value of patents had been left as before, the charges in connection with the maintenance of the patents having this year been paid out of the revenue, as they only amounted to about £70. It had not been necessary to augment the suspense account as a result of this year's working, but an item which previously appeared under another heading was considered by the auditors to fall under the suspense account owing to the alterations introduced under the new working agreement with the Allgemeine Elektricitäts-Gesellschaft, and was accordingly so transferred. He was pleased to say that the working arrangement made with the Allgemeine Elektricitäts-Gesellschaft had resulted in the continuance of friendly relations, and he was satisfied that they were doing their very best to improve the quality of the lamps sent out. With regard to the progress of the lamp, the following extract from the last report of the Allgemeine Electricitäts Gesellschaft would be of interest: "The Nernst lamp, as regards its durability and the life of the burners, has been further improved, and is showing good results, particularly on the higher volt circuits so general now on modern installations. A new type of lamp for 250 candles, also a candle lamp, and lamps suitable for searchlights have been placed on the market. Up to now approximately 2,000,000 of lamps and burners have been sent out, and the demand is increasing." Continuing, the Chairman said there was no doubt that the lamp did consume about half the current required by carbon lamps for the production of an equivalent amount of light. On the other hand, it was a more delicate piece of apparatus than the ordinary lamp, and hence required very skilful handling. For these reasons he thought they ought to appreciate the fact that the original hopes formed at the time the invention was made—namely, that it would create a complete revolution in the industry—would not be realised by the lamp in its present form. It, however, fulfilled a most useful purpose, and he had little doubt that the sale would increase, especially in quarters where the generating stations had been well designed and the staff were possessed of good electrical knowledge. In view of the above, they were again brought face to face with the difficult problem of the value at which the patents stood in the books. A provisional suggestion had been made that the capital be reduced to £100,000; and although a circular was sent out on the basis of a reduction to £50,000 to meet the views of an important section, it remained for the shareholders, with the knowledge now before them, to decide which alternative they preferred. The result of the circular sent out showed that only the holders of some 10,000 shares out of 320,000 were opposed to the scheme. On the other hand, a considerable number, as might have been expected, did not reply, and it was, therefore, impossible to say whether they could go to the courts as a united body with a request that they would grant the reduction they desired. Another course open to them was liquidation and reconstruction, which could be carried by a three-fourths majority; but if they could only agree, they should hope by the first process to effect their purpose by the expenditure of a few hundred pounds, whereas the second course would involve more than this sum in stamp duties and registration fees alone. On one point, however, there seemed to be no doubt — namely, that the directors would not, under existing circumstances, be justified in dividing any profits made until the losses of the past had been met. These losses, with the depreciation which would have to be faced, would mean that the shareholders would all have to wait some years before they could hope to receive any return on their money, if they decided to leave things as they were. Although, therefore, the directors did not feel that they should do more than advise the shareholders in this matter to the best of their ability, and subsequently to spare no efforts to carry their wishes into effect, he must say that, personally, he should like to see the Company put on a proper commercial footing without further delay.

Mr. J. G Dalzell seconded the motion, which was adopted.

Mr. Langham Reed then moved: "That the shareholders of this Company desire that the capital of the Company should be reduced to £100,000, in ordinary shares of £1 each, all one class; that the preference shareholders shall receive, as nearly as may be, £75,000 and the ordinary shareholders £25,000, and that the directors be requested to take such steps as they may be advised are necessary for the reduction of the capital of the Company on the basis of this resolution."

Sir Henry Mance seconded the motion, which was ultimately agreed to, with two dissentients.

INDIARUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS.

Presiding at the ordinary general meeting of this Company on Tuesday, **Major Leonard Darwin** said they were not at the present moment engaged in any work of great importance, and he could not prophesy what might be in store for them during the coming year. Since the ordinary general meeting, held about a year ago, legal sanction had been received to the amendment of the Company's memorandum of association, and the Board had under preparation a new set of articles of association, which would be more in accordance with existing wants and practice. The present articles of the Company were about 40 years old, and they had been altered from time to time in such a way that reference to them in their present state was very troublesome, and misunderstandings and mistakes were liable to occur. Their solicitors had prepared the drafts. The directors thought that the shareholders were to be congratulated on the results of the past year's working, as, while paying the usual dividend of 10 per cent. for the year, the Board had written off buildings, machinery, and ships £46,150, or about £26,000 in excess of the usual annual depreciation. The general business had fallen off in bulk when compared with that of the previous year, and competition had been keen. In one "line," which was not an inconsiderable one, they had been beaten by German manufacturers, who, the Board believed, were selling, under the cartel system in vogue among them, about 18 per cent. cheaper to English consumers than they sold to the German trade. The directors hoped to recover this "line" by new methods of manufacture, while maintaining a good quality of production, as they did in this particular article on a previous occasion. The laying of the San Francisco-Honolulu cable was successfully accomplished shortly after the Board met the shareholders a year ago, and it had since continued to give every satisfaction to the Commercial Pacific Cable Company. The works at Silvertown and Persan were in an efficient state, but it would be necessary to make some further additions to the plant if, as the directors anticipated, the new motor tyre referred to in their report met with the approval of the motoring public. The chairman of the Company, Mr. Henry Marsham, was absent on a tour in Japan, and would doubtless make their name and the nature of their manufactures known to many in the districts he would visit. He concluded by moving the adoption of the report and accounts and the payment of a dividend of 15s. a share, tax free.

Mr. George Henderson seconded the motion, which was adopted.

ARON ELECTRICITY METER.

The ordinary general meeting of the shareholders in this Company was held at Winchester House on the 10th inst., Mr. H. Hirst presiding.

In moving the adoption of the report, the **Chairman** reminded the shareholders that there was a loss last year of £6,032, while £2,500 had to be paid out of capital towards sinking fund. This year, after a liberal writing off, they had made no loss, and had been able to provide practically the whole of the sinking fund out of the profits. The balance-sheet for the past year was a healthy one, comparing it with that of 1902, in so far as there had been ample depreciation, and the decrease in stock and sundry debtors of £9,370 was represented by about £10,000 additional hard cash. The results would have have been better but for three particular causes, which showed themselves in the shape of expenses against the year's trading. First, the stagnation in business last year led the directors to make serious efforts to endeavour to apply some of the unused capital at their disposal for new enterprises, none of which, however, were sufficiently encouraging to warrant them in investing any of the Company's capital in them. The second cause was the continuance of experiments with a new meter and the taking out of patents for it. He explained to them last year that the larger quantity of very small meters required owing to the change of voltage in stations all the world over, had been a reason why the Company were kept out of a great many stations, as their meter could not compete in price satisfactorily for the smallest sizes. Dr. Aron had succeeded in finishing what appeared to be an excellent little meter for alternating currents, and it would very shortly be on the market. He was satisfied with the technical success of the meter, while so far as he (the speaker) could judge as a manufacturer, he believed that the Company would be able to produce it sufficiently cheaply to compete. The third item which had worked against this year's profit was the expenditure of several thousand pounds for the purpose of making good the meters in

Digitized by Google

this country which they supplied two or three years ago, and which developed faults in practical use. The Company had liquid assets amounting to £75,455, against which there were the debenture issue, £56,900, and creditors, £5,444, leaving a net balance of £13,111, without any valuation of land, freehold buildings, machinery, tools, fixtures, patents, or goodwill and stock, the stock alone amounting to £37,560. On a recent visit with Mr. Blumlein to Germany, he convinced himself that the Company had an excellent property in Schweidnitz, and that it had considerably improved in value. They sanctioned an expenditure of £2,500 for an extension of works in which to manufacture the new small meter. As regarded the commercial outlook in Germany they had been eminently successful, especially during the latter half of last year. They supplied 150 stations in that country, and had increased their business with nearly all of them. The Physikalisch Technisch Reichanstalt had, on behalf of the German authorities, passed the Company's meter for both alternating and continuous currents. In Austria and France they had held their own. In this country they were in rather a peculiar position. A few stations which had used their meters largely had again returned to them A great number of engineers, however, were so discouraged about 15 or 18 months ago that they had not returned to them, although the meters were now giving most satisfactory results. The Company would have more chance of regaining their support if they could supply both large and small meters, and the Board would make every effort to do this as soon as the small meter was on the market. An effort was now being made to bring more "life" into the American business.

Sir James Pender seconded the motion, which was adopted.

DOUGLAS SOUTHERN ELECTRIC TRAMWAYS.

The annual meeting of the shareholders in this Company was held in Manchester, Mr. T. J. Hutchinson presiding.

The **Chairman** said the directors were satisfied with the state of the undertaking. Notwithstanding the bad weather of last season the tramways had done exceedingly well. It was hoped that next year they would be able to pay a dividend upon the ordinary shares. In reply to a shareholder, the Chairman explained why nothing was set aside for depreciation of plant and permanent way. The undertaking had only finished its eighth year. But the line was not worked 365 days in the year; its season only lasted 120 or 130 days. In the whole eight years the trams had only run 960 days, or less than three years. Each of these days had not been above six hours in length on an average, and so it might be said that the permanent way and plant had only had two years' real hard wear and tear. In mileage they got from each car only a sixth of a year's work. Then considerable expense had been incurred from year to year in repairs and renewals, and the Company kept a small staff at work all through the year improving and repairing the plant. Moreover, at the end of 10 years from the start—or in two years from now—the Company could demand to have the whole undertaking purchased by the Marine Drive Company at cost price, or in the alternative further running powers over the Marine Drive for 21 years. The proper time for considering the depreciation question would be when the present lease from the Marine Drive Company had expired, and the Marine Drive Company had decided to give another lease rather than purchase the undertaking. A dividend of 7 per cent. on the preference shares was declared.

BRITISH ELECTRIC TRACTION.

The interim report of the directors states that, having regard to the very unfavourable weather which has prevailed throughout the year, the traffic receipts of the various associated undertakings on the whole show satisfactory increases. During the present year over 50 route miles of new or reconstructed tramways or light railways have been opened for traffic by electric traction on the overhead system. The policy of the directors for some time past has been to restrict as much as possible the further capital commitments of the Company on new schemes or extensions, and the attention of the management is now mainly concentrated upon increasing the revenue from the Company's present investments. No portion of the additional debenture capital authorised at the last general meeting has yet been issued. The Auckland Electric Tramways Company, Limited (New Zealand), in which the Company has an interest of nearly £300,000, has been successfully established. Some of the lines were opened for traffic at the end of last year, and others during the present year. The traffic receipts are satisfactory, and in excess of the estimates, and it is expected that a dividend will be paid on the ordinary shares of the Auckland Company for this, the first year of working by electric traction. The business of the Metropolitan Electric Tramways, Limited, in which the Company holds shares to the amount of about £219,000, and has guaranteed to raise further capital to the extent of about £300,000, is also developing satisfactorily. That company will eventually operate in the important area north of London about 48 miles of light railways, under leases from the County Councils of Middlesex and Hertford, in conjunction with its own 8¼ miles of tramways. It also holds about 70 per cent. of the capital of the North Metropolitan Tramways Company and all the issued share capital of the North Metropolitan Electric Power Supply Company, which latter company owns Acts of Parliament authorising the supply in perpetuity of electricity in bulk in an area of about 325 square miles in Middlesex, Hertford, and Essex. Considerable progress is being made by the County Council of Middlesex and by the Metropolitan Company in the construction of lines and works, and it is hoped that about 20 miles of lines will be opened for traffic by electricity on the overhead system early next summer. Arrangements are in progress for the consolidation of the Company's interests in the various associated companies in Birmingham and adjacent districts, now operating about 90 route miles of tramways and light railways. During the past session the Company has obtained an Act of Parliament authorising the reconstruction for working by electric traction of the existing Brighton and Shoreham tramways and extensions of the lines to Worthing. The tenure of the greater part of the lines is for 42 years, and the Company has obtained a favourable purchase clause. The Company has also obtained an Act of Parliament authorising the construction of further tramways in the neighbourhood of Croydon, forming extensions of the existing Croydon electric tramways, thus completing an important network of tramways of about 30 route miles.

ISLE OF THANET ELECTRIC TRAMWAYS AND LIGHTING.

The ordinary meeting of the shareholders in this Company was held on Wednesday at Salisbury House, London-wall, Lord Arthur Butler presiding

The **Chairman**, in moving the adoption of the report, said that the past summer had been most disastrous as regards receipts for an undertaking such as theirs, which mainly depended for its revenue on the influx of visitors to the Isle of Thanet during the summer and autumn months. Considering that the difference between the receipts in a fine and in a wet week during the season would run into from £300 to £400, it was impossible to show the returns they would like to unless there was favourable weather. The lighting receipts were, of course, only in their infancy Mains were now being put down in the Margate area, where there was a considerable demand for electric lighting, which should improve the Company's receipts materially next year. The accrued interest due on Sept. 30 to debenture holders and preference shareholders had been met. From the sum of £10,804 brought forward from last year's revenue account, £1,853 had been deducted, the bulk of which consisted of compensation for injuries and legal charges resulting from the unfortunate accident in August, 1901. An amount of £3,403 had been carried to appropriation account to meet various charges, leaving £5,047 to be carried forward. The traffic receipts for the period under review were £33,465, against £35,088, being a decrease of £1,623 on the year. The number of passengers carried, 4,406,821, showed a falling off of 165,575. It would be interesting to the shareholders to know that the highest single day's takings since the opening of the line was on August Bank Holiday of this year, when the amount was £452, and the lowest on record, £14. 6s. 1d., was on Dec. 5, 1902, when the line was practically snowed up.

Mr. A. Wright seconded the motion, which was agreed to.

An extraordinary general meeting was afterwards held to consider a Bill which is being promoted in the next session of Parliament in the name of the Company. It was explained that the Bill, though in the Company's name, was being promoted at the risk and expense of the contractor, the object being to overcome a technical difficulty with regard to the acquisition of certain land. The Bill was approved.

BLACKPOOL, ST. ANNES, AND LYTHAM TRAMWAY

The directors have issued their annual report, which states that the work of doubling the line and equipping it for the overhead traction system has been proceeded with. In the latter part of June the line was opened so far as it was then available, but with a supply of cars totally insufficient for the business offered. Still, the directors report that the receipts have more than come up to their expectations, and the traffic done, they add, augurs well for the future returns. The completion of the contract with the Blackpool Electric Tramways (South), Limited, had not taken place when the books of the Company were closed, so that the items of capital and capital expenditure present a somewhat different aspect on the balance-sheet from what they will in the future. The cost of property is set down at £109,745. The purchase of the undertaking and additions come to £122,679; and various additions, including £3,742 for the cost of obtaining the Parliamentary Bill in 1900, and £2,578 for plant and machinery, make a total of £133,134. But against this are other items, including £21,971 put to the suspense account, which total £23,388. The suspense account mainly consists of £14,319 loss on the sale of gas cars, £2,778 loss in realising on the plant and machinery, £1,700 loss on the damage to the depôt by the storm, and £2,013 for preliminary expenses. Stock is valued at £836, and £2,365 stands for the parliamentary deposit on the new Bill. Money owing to the Company amounts to £1,390, and there is £7,110 with the bank and in hand. The traffic receipts show the good return of £13,386, whilst advertisements and other receipts brought in £144. The working expenses took £7,314, and salaries, etc., £1,020. A balance of £5,196 is left, and with other items it is raised to £5,936. Interest on debentures claims £3,559, and law costs £359, so that £2,017 is actually left for balance, and this, the directors recommend, should be carried forward. There is £4,800 due for arrears on dividend, and other claims against the Company amount to £241.

ARC LAMPS.

The report of the directors for the year ended July 31 last, presented at the meeting on the 17th inst., stated that the gross profit for the period was £5,835, as compared with £3,989 for the year to July 31, 1902. After payment of all expenses of management, and after substantially depreciating machinery and plant, the surplus was £2,639. Mr. Davy had, as the result of extensive experiments, made important discoveries, and again added to the patents held by the company, but mention need only be made of the 1904 type of lamp, which was now being placed on the market. For the third time in the history of the company it had become necessary to extend the works, and negotiations were proceeding for the acquisition of the additional premises. In March last the Jandus Arc Lamp and Electric Light Company, Limited

Digitized by Google

issued a writ against this Company, alleging infringement of certain letters patent owned by them, and a statement of claim was duly delivered in June. After deferring the trial of their action as long as they possibly could, the plaintiffs applied for leave to still further postpone for the purpose of amending their patents, and permission was granted on Nov. 18 by the judge on certain terms, one being to the effect that all amendments to the specifications (which can only be made by way of disclaimer) be made within four months. The directors declared an interim dividend at the rate of 5 per cent. per annum for the first half of the year to July 31, 1903, and the shareholders were asked to sanction a distribution at the rate of 7 per cent. per annum for the second half of the year.

NEW COMPANIES REGISTERED.

Etheridge Railway Company, Limited.—Capital, £30,003. Object: to acquire concessions, rights, and privileges for the construction of railways and tramways in Queensland, or in any other part of the world, etc.

Paine, Mainwaring, and Lephard, Limited.—Capital, £15,000. Object: to carry on the business of machinists, mechanical and electrical engineers, motor and cycle manufacturers, etc. Registered office: Broadwater-street, Broadwater, Worthing.

Britannia Engineering Co., Limited. — Capital, £40,000. Object: to acquire and carry on the business of general engineers, engineers' and machine tool manufacturers, etc., heretofore carried on by T. M. Bear and J. Blomfield, as the Britannia Company, at the Britannia Works, Colchester, etc. Registered office: Britannia Works, Magdalen-street, Colchester.

Goodfellow Engineering Co, Limited. — Capital, £20,000. Object: to carry on the business of iron, steel, and metal manufacturers, merchants, and agents, machine and tool makers, ironfounders, engineers, machinists, millwrights, boiler makers, contractors for refrigerating plant and mill gearing and for fitting up mills, collieries, pumping and electrical stations, tramways, etc. Registered office: 12, Exchange-street, Manchester.

Durham and District Electric Traction Co., Limited.—Capital, £30,000. Object: to carry on the business of carriers of passengers and goods, electrical and general engineers, electricians, contractors, wharfingers, agents, manufacturers of and dealers in railway, tramway, electric, and other apparatus, etc. Registered office: Donington House, Norfolk-street, W.C.

Synchronised Electric Clock Company. — Capital, £2,500. Object: to acquire the following provisional specifications for patents—namely: No. 18,309, dated Aug. 25, 1903, of W. W. G. Webb, J. Hall, and J. F. A. Chandler relating to improvements in clocks; No. 22,858, dated Oct. 22, 1903, of F. A. Chandler and B. Bonnisken for improvements in electrically-synchronised clocks and the like; and No. 24,684, dated Nov. 16, 1903.

Kroeger Light Cure and Electric Therapeutic Institutes, Limited.—Capital, £15,000. Object: to acquire and carry on the businesses heretofore carried on by M. Kroeger at 67, Elizabeth-street, Eaton-square, S.W., and 11, Grand-parade, Eastbourne, by the said M. Kroeger and Mrs. I. Maxwell at 12, Cheniston-gardens, W., and by the said M. Kroeger, A. L. Smith, and Miss E. W. Smith at Mansion House-chambers, 11, Queen Victoria-street, E.C., under the style of Kroeger's Light Cure Institutes.

APPOINTMENTS VACANT.

Surveyor and Electrical Engineer, Boston. Salary, £300. Dec. 18.

Wiremen, and Armature Winders. Apply, Harland and Wolff, Belfast. See advertisement.

Head Draughtsman. Apply to J. H. Holmes and Co., Newcastle-on-Tyne. See advertisement.

Wireman, at the Goldsmiths' Institute, New Cross, to conduct classes in electric wiring. See advertisement in last issue.

Resident Electrical Engineer, Leicester Tramways. Salary, £250, rising by £25 a year to £350. Applications by Jan. 1, 1904. See advertisement.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Paris.—The Post and Telegraph Department, 103, Rue de Grenelle, require tenders for 24 lots of accessories by Dec. 29.

Rome.—The Admiralty require tenders for electric lamps, estimated at £6,000, by Jan. 23. Foreign competitors are invited.

Madrid.—The Public Works Department require tenders for installation and working of electric tramways from Mondariz to Porrino by Feb. 12, 1904.

Barcelona.—The Harbour Works Commissioners require tenders for installation of electric light and power by Feb. 15. Particulars may be obtained from the Commissioners.

Pontypridd.—The Urban District Council invite tenders for free wiring, and for Section O, the supply of tramcars. Tenders by 24th inst. See advertisement in former issue.

Whitby.—Tenders are invited for fitting-up the Whitby Temperance Hall with electric light. Specifications from Mr. A. Palframan, Leesholme, Bagdale, Whitby. Tenders by 19th inst.

Govan.—The Corporation invite tenders for the supply, delivery, and erection of coal bunkers, conveyor, and electric capstan. Tenders by 28th inst. See advertisement in former issue.

North Shields.—Tenders are invited for installation of electric light at the Tynemouth Victoria Jubilee Infirmary. Particulars from Mr. John W. Meadows, 43, Howard-street, North Shields.

Peteringa (Croatia).—The Municipality require tenders for installation and working of electric lighting; 6 to 8 arc and 160 to 180 incandescent lamps are required for the street-lighting.

Blackpool.—The Tramways Committee invite tenders for laying about 1,650 yards of double-line tramway. Specifications, etc., from Mr. John S. Brodie, Town Hall, Blackpool. Tenders by 29th inst.

Greenwich.—The London County Council invite tenders for six electrically-driven three-throw boiler feed pumps. Specifications, etc., at the County Hall, Spring-gardens, S.W. Tenders by Jan. 19.

Plasencia.—The Municipality require tenders for electric lighting of the town for 12 years by 26th inst. Particulars from the above authority, Casas Consistoriales, Plasencia, Province of Carceres, Spain.

London, E.C.—The East Indian Railway Company invite tenders for the supply and delivery of electric plant for a lighting installation. Specifications from Company's Offices. Tenders by 12 noon on 23rd inst.

Irvine (Scotland).—The Corporation invite tenders for providing, erecting, and laying down the whole plant and apparatus necessary for electric light installation. Particulars from Mr. Jas. Dickie, town clerk.

Canterbury.—Tenders are invited for wiring the Kent and Canterbury Hospital for electric lighting, and other works in connection therewith. Specifications from Mr. W. J. Jennings, 4, St. Margaret's-street, Canterbury.

Hackney.—The Council invite tenders for feeding and distributing mains. Specifications from Mr. Robert Hammond, M.I.C.E., 64, Victoria-street, Westminster, S.W. Tenders by Jan. 4, 1904. See advertisement in last issue.

Paris.—The Post and Telegraph Department require tenders for 80,000 km. bronze wire, 1,081,000 km. copper wire, 105,000 porcelain insulators, 250,000 km. galvanised iron wire, by Dec. 28. Particulars, 103, Rue de Grenelle, Paris.

Camberwell.—The Borough Council invite tenders for the maintenance of electric bells and private telephones. Forms of tender from Mr. W. Oxtoby, borough engineer, Town Hall, Camberwell, S.E. Tenders by 5.30 p.m. on Jan. 18.

Sydney (N.S.W.).—Tenders are asked for the supply of continuous and alternating current meters. Specifications, conditions, and forms of tender are obtainable from Messrs. Preece and Cardew, 8, Queen Anne's-gate, S.W. Tenders by Jan. 12.

Christchurch (New Zealand).—Tenders are invited for the complete installation of electrical tramways, other than buildings. Specifications, etc., may be obtained from the Agent-General for New Zealand, Victoria-street, S.W. Tenders by March 17. See advertisement.

Wallasey.—The Urban District Council invite tenders for the supply and delivery of about 7,100 yards concentric armoured cables, together with joint boxes and section boxes. Specifications from Mr. J. A. Crowther, Electric Supply Works, Sea View-road, Liscard. Tenders by Jan. 16.

Culiacan (Mexico).—Tenders are invited for lighting the town by electricity: 60 arc lamps of 1,200 c.p. and 110 incandescents of 50, 30, and 16 c.p. will be required. Propositions will be received by letter until Dec. 31 in the Secretaria del Ayuntamiento, Culiacan, where further information may be obtained.

Long Eaton.—The Urban District Council invite tenders for engine, dynamo (250-kw. set), and accessories, one Lancashire boiler, overhead hand travelling crane, economiser, for the electricity works. Specifications from Mr. Frank Worrall, A.M.I.C.E., Electricity Supply Works, Long Eaton. Tenders by Jan. 1.

Enniscorthy (Ireland).—The District Lunatic Asylum Committee invite tenders for the following works: generator and motor-generator converter; motor and motor pumps; accumulators; main switchboards; overhead conductors and telephone; gearing and shafting; wiring asylum. Specifications, etc., at the Asylum Office. Tenders by Jan. 20.

Sydney (New South Wales).—Tenders will be received at the office of the Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 30, for the supply and delivery at the departmental stores, Sydney, of telegraph, telephone, and electric light material. Specifications, etc., may be seen and tender forms obtained at the General Post Offices, Sydney, Melbourne, Brisbane, Adelaide, Hobart, and Perth.

Harrismith (South Africa).—The Town Council invite tenders for high-tension concentric feeder cable, low-tension triple-concentric distributor cable, low-tension service and street-lighting cables, joint-boxes, service boxes, and other accessories, and the supply of five 30-kw. transformers, four transformer pillars, high and low tension switchgear, etc. Specifications from Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster. Tenders by Jan. 18.

Erith.—The Urban District Council invite tenders for the supply and erection of two Lancashire boilers, with fittings, brickwork settings, and steam feed pump; steam, exhaust, feed, air and circulating, blow-off, and drain pipes; surface condenser, with steam-driven air and circulating pumps; three-phase alternator and direct-coupled high-speed enclosed-type steam-engine of 500 kw. capacity; extensions to main switchboard and cable connections. Tenders by Jan 18. See advertisement.

Digitized by Google

RESULTS OF TENDERS.

Gravesend.—The Town Council have accepted Messrs. Balfour and Sons' tender for tanks, at £178.

Cardiff.—The Tramways Committee have accepted the tender of the British Westinghouse Company for supplying 15 combination cars at a cost of £601. 10s. per car.

Radcliffe (Lancs.).—The Urban District Council have accepted the tender of W. Metcalf, Limited, Church, Lancashire, for the supply of the pitch and oil required in the construction of the tramways.

Yarmouth.—The tender of the British Electric Transformer Company for additional transformers, at £240, has been accepted, and that of Mr. McNaughton, for carbons, at £3. 18s. 9d. per 1,000 pairs.

Portsmouth.—The Telephone Committee have received three tenders for the switchboard extension at the central exchange, and recommend the acceptance of that of the International Electric Company, London, the amount being £645.

Johannesburg (S.A.).—The tender of Bolckow, Vaughan, and Co., Limited, Middlesbrough, has been accepted for tramway rails, fish-plates, and flange rails required by the Corporation. The total quantity required is about 7,000 tons, and the value of the order is over £40,000. The order for the points and crossings has been secured by Hadfield's Steelfoundry Company, Limited, Sheffield.

Maidstone.—The Corporation have received the following tenders for the construction and equipment of light railways:

British Westinghouse Company, Limited, Manchester...	£23,052	5	10
Brush Electrical Engineering Company, Limited, Belvedere-road	21,759	11	5
W. Griffiths and Co., Bishopgate-street Without	21,634	11	11
British Electric Equipment Company, Queen Victoria-street	21,532	8	9
Blackwell and Co., Limited, 59, City-road, E.C.	20,079	3	3
J. G. White and Co., Limited, College-hill, Cannon-street	19,016	1	4
Dick, Kerr, and Co., Limited, Abchurch-yard, Cannon-street*	18,871	3	11

* Accepted subject to confirmation by Council and Board of Trade.

BUSINESS NOTES.

TRACTION.

Walsall.—Dec. 31 has been fixed for the opening of the Walsall tramways.

Leith.—The Town Council have approved the petition for a tramway provisional order.

Portsmouth.—The Town Council have decided to try the use of covers on the cars.

Cheltenham.—The Tramways Committee have agreed to the proposed double line in High-street.

Newcastle.—The Corporation are going to proceed with the tramway extension from Scotswood to Blaydon.

Ardsley.—The proposed extension of the tramways to East Ardsley has been approved by the District Council.

Maidstone.—An extension of time is being applied for by the Maidstone and Faversham Light Railway Company.

Hull.—The Works Committee have given an order for 15 patent Kennington collapsible car covers for the electric tramcars at £80 each.

Mandalay.—*Indian Engineering* states that the Mandalay tramway will be running by April. The manager is expected to arrive this month.

Exeter.—An arbitration has been held to determine the price to be paid by the Corporation for the compulsory purchase of the tramway undertaking.

Warwick.—The Town Council have approved the plans of the proposed tramways. Wood paving is to be laid along the whole line, except at certain specified places.

Hove.—The Town Council have decided to have the existing tramway within the borough valued in the event of their deciding to purchase within the next seven years.

The Lake District.—Two companies are being formed to run a service of motorcars between Windermere Station, on the London and North-Western system, and Keswick and other places in the Lake District.

Electro-Pneumatic Signalling.—The North-Eastern Railway Company have introduced a large installation of electro-pneumatic signalling on their Sunderland and North Shields line at Harton Colliery.

South Bank.—A special meeting of the Urban District Council is to be held to consider the intended application of the Imperial Tramways Company for powers for a tramway extension to South Bank and Eston.

Pemberton.—The new engines which have been installed at the tramway power house will be formally started early next month. The committee are considering the mode of reconstructing the Ormskirk-road route.

Blaydon.—A deputation from the Newcastle Corporation attended the last meeting of the District Council and explained the tramway proposals of the former in that district. The local Council are supporting the scheme.

Beckenham.—The British Electric Traction Company have informed the District Council that "under no circumstances" would they be prepared to entertain the proposal for the conduit system in connection with the projected tramways.

Paisley.—Mr. H. F. Parshall, engineer for the Paisley District Tramways Company, has forwarded to the District Committee of the County Council plans showing the general arrangement of the proposed tramways and overhead construction.

Ipswich.—A trial trip over the Spring-road and Derby-road section of the tramways took place on Tuesday. The Board of Trade inspection of the whole of the lines not previously examined by the inspectors will probably take place on the 23rd inst.

Poplar.—The General Purposes Committee of the Borough Council have approved the plans for the London County Council electric tramways to be constructed along East India Dock-road, and the proposed extension to the Iron Bridge. The conduit system is to be adopted.

Lambeth.—The Borough Council have declined to agree to contribute more than £20,000 towards the cost of the street widenings in connection with the tramway reconstruction. This is only one-sixth of the total amount, whereas the County Council require a one-third contribution.

South Shields.—The scheme for electric tramways has so far advanced that the Tramways Committee will recommend to the next meeting of the Town Council that tenders be invited, to include offers for the leasing, as well as for the construction and electrical equipment of the tramways.

Llanelly.—At a meeting of the Urban District Council on Monday the proposal to promote a Bill in Parliament for the specific performance of the agreement between the Council and the British Insulated Wire Company failed to get the required support, and the application will have to be dropped.

Glasgow.—The Glasgow Chamber of Commerce have passed a resolution deciding to petition the Corporation in favour of withdrawing the present proposed provisional order in so far as the extension of the present tramway system is concerned until the ratepayers have had reasonable time to consider the Bill.

Everton.—The Tramways Committee of the Liverpool Corporation have postponed for a month the consideration of the general manager's report on the Everton tramways. They have had under discussion the report of the general manager as to the results of working the Everton experimental routes. The routes are to be discontinued.

Wolverhampton.—A long discussion took place at the last meeting of the Town Council on Monday with regard to the recent suspension of the service on a section of the new Hampton-road route. It was explained that the committee decided on this course from anxiety for the ratepayers' interest, and their action was ultimately approved.

Southwark.—The County Council have informed the Borough Council that all that is possible will be done to relieve the inconvenience caused to the public by the electrification of the tramways in the district. Some of the traffic will be diverted to secondary streets, whilst the whole work will be completed as rapidly as possible.

Tube Breakdown.—On Wednesday morning, at five minutes to nine, a train on the Central London Railway, bound Citywards, broke down near the Marble Arch, owing, it is stated, to some slight defect in the motor equipment. As quickly as possible the train was shunted to a siding, and the passengers transferred to another train. There was very little delay.

Chester.—The Tramways Committee have resolved: "That it be recommended to the Council that the committee be authorised to advertise for tenders and enter into a contract for the privilege of advertising on the tramcars for three, five, and seven years respectively, the advertisements to be placed on outside boards and the ventilator windows only."

Hammersmith.—At the last meeting of the Borough Council, Mr. Collins, L.C.C., said the London County Council were short of money, and it rested with that Council to find the money for the proposed tramway from Hammersmith to Harrow-road, or he was afraid it would be deferred for a considerable time. It was decided to leave the matter in the hands of the Special Purposes Committee.

Cape Electric Tramways.—The directors of the Cape Electric Tramways, Limited, have declared an interim dividend of 5 per cent., payable to shareholders registered on the 24th inst., and to holders of coupon No. 16 attached to share warrants to bearer. The transfer register will be closed from Dec. 24 to 31 inclusive. The dividend will be payable after the receipt of transfer returns from South Africa.

Barrow.—Good progress has been made in electrifying the tramways, and it is expected the first run by the new electric cars will be made before the end of the present month. The suggestion that the Dalton Council should approach the British Electric Traction Company with a view to obtaining an extension of the tram service as far as Dalton has met with great favour among the residents of Barrow and Dalton.

Argentine.—The City of Buenos Ayres Tramways Company, Limited, states that negotiations have been opened with a view to the transfer of the company's undertaking to the Anglo-Argentine Tramways Company, Limited. The Board favourably regards these proposals, and as soon as a provisional agreement has been concluded an extraordinary general meeting of the shareholders will be called for its consideration.

Sheffield.—Satisfactory progress is being made with the extensions of the tramcar sheds at Queen's-road, Sheffield. The cost will amount to about £20,000, and the work is being carried out by Messrs. T. Roper and Sons, under the supervision of the city surveyor. The new sheds

Digitized by Google

will be ready for occupation in the spring of next year. The tramways department have now 215 cars running, but this number will probably soon be increased.

Bradford.—Major Pringle has inspected the new tramway laid by the Corporation in Church-bank, which is the steepest gradient in the city—namely, 1 in 9—and serves two termini. Major Pringle expressed himself satisfied with both sections, and sanctioned a speed of four miles per hour on the Church-bank portion. The public cars will start running to Undercliffe, *via* Church-bank, as soon as the Board of Trade certificate is received.

Derbyshire Light Railways.—The Light Railway Commissioners have granted the draft order relating to the proposed electric railway in Derbyshire from Hope to Bradwell and Castleton. The line is to be connected with the Dore and Chinley Railway, a short distance from Hope Station, and the terminal station will be at Castleton. The power station will be near Greyditch. The total estimated cost of the new line is a little under £40,000.

Islington.—A communication received from the Board of Trade with reference to the London County Council's application to lay a tramway in Rosebery-avenue, St. John-street, and St. John-street-road, was referred to the Works Committee, with power to act. At the last meeting of the Borough Council the Council decided any other than the conduit system for the tramways proposed to be laid down in Islington would be "detrimental to the best interests of the borough."

Ayr.—Colonel Yorke has inspected the Corporation electric tramway system with a view to increasing the speed over the whole route. Colonel Yorke was satisfied that an increase of speed was justifiable. The total length of the system is over 5½ miles, and with the exception of half a mile from the north end of the new bridge along High-street and Alloway-street to the Burns Station, the speed is to be increased from 10 to 12 miles, which will greatly facilitate the efficiency of the service.

Yarmouth.—Acting on a hint from the Board of Trade, the Tramways Committee have passed a resolution the effect of which is that on occasions of exceptional traffic or inclement weather conductors may admit seven persons into the interior of a car when the maximum seating accommodation is already occupied. A hitch has occurred in the negotiations for the purchase of the Gorleston and Southtown Tramways, and the Corporation have decided to take no further action in the matter.

Plymouth.—The Borough Council at their last meeting decided that an application be made to the Board of Trade for a provisional order to authorise the Council to construct four additional tramlines in the borough. Three of the proposed new tramways are short lengths in connection with the Old Town-street and Tavistock-road improvements already approved by the Council. The net increase of receipts for the past five weeks over the corresponding five weeks in 1902 was £283.

Manchester.—The Watch Committee have decided to rescind their resolution of December last year in favour of allowing an excess number of passengers in the electric cars during "rush" hours in wet weather, and in future the practice will be discontinued. The Tramways Committee have under consideration the purchase of 100 large cars. Designs have already been submitted to the committee, and it is hoped that when they are put in service the present congestion on several of the routes will be much relieved.

Cardiff.—The Tramways Committee's proposals for revised fares to come into force on Jan 1, have been referred back for further consideration. It was decided at a meeting of the Tramways Committee on Tuesday to extend the tramways from Castle-road to Crwys-road, over the Rhymney Railway bridge, and from the latter place to Talygarn-street, at a cost, including car and electrical equipment, of £12,218, and further, from the present Cowbridge-road terminus to west of Victoria Park, Canton, at an expenditure of £5,455.

Spen Valley.—A sub-committee of the Cleckheaton District Council have had an interview with Mr. E. A. Paris, local manager of the British Electric Traction Company, with reference to the reported intention of the company to postpone indefinitely the construction of the Hartshead Moor section of their scheme. It is stated that Mr. Paris holds out no hope of the whole undertaking being proceeded with yet, but that the present intention is to construct a line along Westgate, Cleckheaton, as far as the Punch Bowl Hotel, in the coming spring.

Reading.—Last week the tramway employés of the Corporation had a social gathering and entertainment in the clubroom of the tramway depôt in Mill-lane. A social and athletic club has been started for the men, thanks to the consideration of the manager (Mr. W. Binns) and the help of many members of the Town Council and others, and it was under the auspices of this club that the entertainment was held. Both the tramways manager and the assistant electrical engineer (Mr. A. Shearer) were present, and great interest was shown in the proceedings.

Aston.—The reconstruction of the tramway route is, so far as the portion in the city of Birmingham is concerned, expected to be completed by the last day of the present year, when the lease expires, and the line will be worked by the Corporation. In Aston Manor, however, the work of transformation is not so well advanced, and probably an additional month will elapse before the British Electric Traction Company, to whom the Aston authorities have leased their interests, will be able to join with the Corporation of Birmingham in a through service to the Lower Grounds and Whitton.

Darwen.—At the monthly meeting of the Town Council the Chairman of the Tramways Committee said that in September last year the net loss on the main section of the tramways was £214. 0s. 10½d., and this year at the end of September the net loss was £120. 15s. 4½d., showing a net loss this year of £93. 5s. 6d. less than last year. On the Hoddlesden section at the end of the same month last year the net loss was £118. 1s. 11d., and this year at the end of September it was £108. 1s. 1d., a sum which included £75 for depreciation, showing that the section was £85 better than at the end of September last year.

Dunedin (N.Z.).—Rapid progress is being made with Dunedin electric tramways. There is about 5¼ miles of single track of permanent way constructed, and the work of construction in the North-East Valley is being pushed ahead, a start having been made at Normanby. The overhead construction is well in hand. In the power station the first unit is erected, and the second unit will shortly be on its foundations. The "Rangatira" also brings the balance of the motor equipments for the cars. It is expected to have steam on the first unit in about a fortnight or three weeks' time.—*New Zealand Mining Journal, Oct. 24.*

Lowestoft.—The general manager of the tramways reports that the total receipts from July 22 to Nov. 24 amounted to £4,841. 0s. 4d.; passengers carried, 1,058,842; total mileage run, 88,672 miles; average receipts per day, £38. 8s. 4d.; average receipts per car mile, 13·10d. The surveyor and general manager have been instructed to confer and prepare a plan for widening London-road and St. Peter's-street, opposite the Triangle, and to submit the plan and estimates of the expense to the next meeting of the Tramways Committee. The new Willans engine is now running at the power station. The British Westinghouse Company have agreed to deliver the new cars in February.

Camberwell.—With respect to the proposed acquisition and electrification of the London southern tramways by the London County Council, the Borough Council have agreed to give their consent to the working of the lines by the overhead system, subject to the point of transfer from the underground conduit to the overhead system being at a point in Coldharbour-lane about midway between Valmar-road and Crawford-street, and to the doubling of the existing lines where proposed by the London County Council. The Council have also agreed to contribute one-third of the cost of the street widenings in the borough in connection with the proposed tramway from Lordship-lane to Forest Hill.

South Lancs.—The South Lancashire Tramways Company are proceeding with the construction of several extensions of their existing tramways. It is intended in the first instance to begin the extension from Tyldesley to Worsley boundary at Boothstown, from Hindley, *via* Westhoughton, to the Bolton Corporation boundary at Deane, and from the Leigh boundary to St. Mary's railway station, Lowton. These will be constructed immediately and will be followed by the equipment of the routes from Four Lane Ends, Hulton, *via* Little Hulton and Walkden to Swinton, from Boothstown to Irlams-o'-th'-Height, and from Lowton to Newton-le-Willows. The extensions comprise about 40 miles of tramways.

Additional Traffic Returns.—Anglo-Argentine, £1,875 increase; Barcelona Ensanche y Gracia, £88 increase; Barcelona, £48 increase; Brisbane, £73 decrease (month of November, £10,544, increase £253), British Columbia Electric (month of March), gross earnings £10,352, net income £2,659; Buenos Ayres and Belgrano Electric, £166 decrease (month of November, £14,142, increase £444); Calcutta, £261 increase; Cape Town (month of November), receipts £16,785, expenditure £8 673; Isle of Thanet Electric, £10 increase; Lisbon Electric (month of October), receipts 93,725 milreis, expenses 50,350 milreis; Mexico Electric (month of November), receipts £47,350, expenses £27,600; Perth Electric, £249 increase; Port Elizabeth (month of November), receipts £4,073, expenditure £2,989.

Huddersfield.—At Wednesday's meeting of the Town Council a long discussion ensued upon a proposal of the Tramways Committee to rearrange the distances and fares for workmen. The facilities are to be increased by allowing workmen to return at any hour between 5.30 p.m. and 7.30 p.m. at the top of any car. On those routes where the ordinary fares are in excess of those authorised by Parliament for workmen, special cars will be run. The chairman of the committee said that their chief point had been to increase the revenue if possible, whilst giving every facility they could to workmen, and also to prevent those who were not workmen from taking advantage of the cheaper rates. The tramway receipts were nearly double what they were three years ago, when the fares were double what they were now, and they were carrying 12,000,000 passengers a year, against 4,500,000. An amendment of Mr. Oxley, which was to be submitted, was, he said, based upon the Glasgow system of fares, which could not be made to apply to Huddersfield, with a much smaller population, but a proportionately larger area.

Birmingham.—It is officially announced that the Birmingham and Midland Tramways Company have entered into a provisional agreement with the British Electric Traction Company to acquire certain of that company in the following tramway companies in Birmingham and adjacent districts: the Dudley, Stourbridge, and District Electric Traction Company, the South Staffs Tramways (Lessee) Company, Wolverhampton District Electric Tramways Company, the City of Birmingham Tramways Company. The effect of the proposals will be to give the Birmingham and Midland Company controlling interests in the various tramway and light railway companies in Birmingham and adjacent districts. These companies are at present operating an aggregate of 90 route miles of tramways and light railways, and have obtained powers for constructing 31 route miles of new tramways and light railways. The majority of these tramways and light railways are already working by electric traction on the overhead system. The directors firmly believe that this consolidation of interests will lead to increased efficiency and economy, while enabling greater facilities to be offered to the travelling public by interchange of cars and otherwise.

Westinghouse Single-Phase System of Traction.—The Westinghouse Company have furnished us with details regarding their new single-phase system of traction, which is said to be specially suitable for the electrification of main steam railways. The company, who have an experimental line at Pittsburg, claim to have successfully over-

Digitized by Google

come all difficulties; and their system is now ripe for application on the most extensive scale. The primary advantages claimed for the single-phase over the direct-current system at present in vogue are that it costs less to instal and less to work, the amount of electrical energy required for a given service being considerably reduced. A high acceleration and retardation are possible, this being a *sine qua non* for short railways with many stations close together, and these are secured without the unpleasant jolting and jerking. The heaviest trains can be dealt with, and high speeds developed, so that the system is admirably fitted for the operation of main as well as of local lines. The public safety is enhanced by the simplification of the controlling gear, and the absence of electrolytic troubles removes many difficulties which beset the laying-out of direct-current lines. The special type of single-phase motor which has been devised is said to have many advantages over the direct-current series motor. Thus the efficiency is higher at low speeds, the speed being regulated by varying the terminal voltage. The frequency employed is 25 cycles. The abolition of the rotary converter effects a great saving of power, and the complications and losses of the series-parallel system of control are entirely eliminated, the motors being connected permanently in series or in parallel, according to the working voltage used. In either case the voltage at the motors is lower than in direct-current work, so that insulation difficulties are minimised, and the liability to burn out is almost negligible. Furthermore, as the motors are in a secondary circuit, of which the line is the primary, the chances of damage thereto from lightning are greatly reduced. These motors and their controlling gear are specially adaptable to the multiple-unit system of control.

London County Council.—At the usual weekly meeting of the London County Council on Tuesday the Highways Committee presented another report with reference to the proposed acquisition of the London Southern Tramways Company's undertaking. The Lambeth Borough Council have not yet agreed to make the one-third contribution towards the estimated cost of the necessary street wideuings as required by the County Council, and the committee stated that they cannot recommend the Council to purchase the undertaking unless the Borough Council will do this and also agree to the use of the overhead trolley system except on the lines in South Lambeth-road. On Dec 22 a special meeting of the County Council will be held to decide the question of purchase one way or the other, and the Borough Council have been given till that date to make up their minds. The Camberwell Borough Council have already given their consent to the use of the overhead system, and no street widenings will be required in that borough. The Council, on the recommendation of the committee, decided to pay a sum of £300 to Mr. Alfred Baker as an honorarium in respect of the services rendered by him subsequent to his relinquishment of the position of tramways manager on Oct. 1 last A new by-law has been adopted by the Council, on the suggestion of the Board of Trade, to the effect "that the rate of speed to be observed for tramway traffic worked by animal or cable power shall in no case exceed nine miles an hour." The Council approved the Tramways and Improvement Bill for the construction of 16 new tramways and the extension and doubling of existing lines, including the Hampstead to Oxford-street, Westminster Bridge-road to the Strand *vid* the Embankment, and the Marble Arch to Cricklewood lines. Mr. Napier, the chairman of the committee, dealing with the matter, reported that some slight friction had occurred with the St. Marylebone authorities in connection with the last-named line, but it was expected that it could be overcome. The full list of the proposed tramways was given in a recent issue of this journal. The following report relative to the reconstruction for electrical traction of the cable tramways from Kennington to Streatham was brought up by the Highways Committee, and adjourned till next meeting: "In the report presented by us on Nov. 24, 1903, with regard to the rebuilding, for the accommodation of electrical cars for use on the tramways between Kennington and Streatham, of the existing car-sheds at Streatham, we stated that we proposed to submit at an early date proposals for the reconstruction of these tramways (about seven miles of single line) for electrical traction. It is of great importance that this work should be completed with as little delay as possible, owing to the inconvenience which results from dealing with the traffic on these lines, which are now worked by cable traction, in conjunction with the lines which are worked by electrical traction. An arrangement is now in force by which passengers on the Streatham lines who desire to travel to the various London termini have to change into the electrical cars at Kennington-gate, a course entailing grave inconvenience and discomfort, and, moreover, the receipts from the tramways are diminished owing to the absence of through car services. We therefore suggest that the Council should at once approve the necessary expenditure for the reconstruction of the lines referred to, for the conduit system of electrical traction, and that the work should be put in hand early in 1904. The Board of Trade has approved of the system to be adopted for the reconstruction of the lines. We propose that the work, when once commenced, should be carried through with as much expedition as is practicable, both in order to minimise the inconvenience caused to the residents along the route by the disturbance of the carriageway, and also to ensure, if possible, that the lines shall be ready for electrical working before the heavy summer traffic commences. We have had before us a suggestion that the present conduit, along which the cable runs, might be utilised in connection with the reconstruction of the tramways; but, after very careful consideration, we have come to the conclusion that this could not be done, the conduit being too small for the underground system of electrical traction. The approximate cost of the road work portion of the reconstruction of the lines, including platelaying, paving works, etc., is £90,000, and we have to ask the Council to pass a vote for that amount. This sum does not include the cost of the rails, estimated at £17,300, which is provided for in the estimate of £90,000, approved on Nov. 17, 1903, for the purchase of rails for these and other lines. Pending the completion of the Greenwich electricity generating station, we propose to make temporary arrangements for the supply of power for working the lines. The cost which will be incurred for this purpose will probably not exceed £500, and will be charged to maintenance account. The electrical cars required for the working of the Streatham lines have been obtained under a contract entered into in pursuance of the resolution of the Council of July 29, 1902, at a cost of £47,686, and these will be ready for use by the time the lines are reconstructed. We have forwarded to the Finance Committee an estimate for £90,000, the approximate cost, as stated above, of the excavation, platelaying, etc., in connection with the reconstruction of the seven miles of single line above referred to; and we recommend that the estimate of £90,000 submitted by the Finance Committee be approved, and that expenditure on capital account of sums not exceeding that amount in all be authorised in connection with the reconstruction for the conduit system of electrical traction of the cable tramways between Kennington and Streatham."

LIGHTING AND GENERAL.

Kirkcaldy.—A day rate of 1½d. per unit is to be charged for power consumers.

Sale of Plant.—Particulars of the sale of a complete electrical plant appear in another column.

Banbury.—The proposed electric lighting of the municipal buildings is before the Town Hall Committee.

Leigh.—The Town Council have resolved to apply for sanction to borrow £8,280 for electricity works extensions.

Barnstaple.—The Electric Lighting Committee are seeking to raise £5,400 for the extension of mains in the outside area.

Hampton.—The electric light company have promised to supply electricity for the new isolation hospital next February.

Middlesbrough.—Application is to be made for sanction to borrow £16,000 to cover the cost of the extension of plant and buildings.

Epsom.—An enquiry has been held into the Urban District Council's application for sanction to borrow £5,930 for electric supply purposes.

Walton.—The Urban District Council have finally decided to apply for a provisional order for electric lighting powers for their area.

Whitehaven.—The engineer is preparing a report for the next meeting upon the cost of laying public and private lighting mains to Kells.

Blaydon.—Arrangements have been made with the owners of Priestman Collieries for the provision and lighting of electric street lamps.

Penrith.—The Urban District Council have adopted an electricity supply scheme, as suggested by the engineers, at the estimated cost of £7,507.

Metropolitan Asylums Board.—The estimated cost of the generating plant and electric wiring for the Grove and Fountain Hospitals is £4,300.

Elland.—The Water and Lighting Committee have decided to light Huddersfield-road from the Weel-yan chapel to the town hall with electricity.

Eastern Telegraph Co.—The directors announce an interim dividend of 1½ per cent. on the ordinary stock in respect of the quarter ended Sept. 30 last.

Nantwich.—The Urban District Council are communicating with the Board of Trade with reference to the extension of the period for the electric lighting order.

Concert.—The employés of the "Robertson" Electric Lamp Works are holding a concert on Saturday, Dec. 19, at 7.30 p.m., in the dining hall at the works at Brook Green.

Insulating Compound.—Messrs. Rowland Carr and Co. have again secured the annual contract for the supply of insulating compound for the National Telephone Company.

Trowbridge.—The Council have appointed Mr. George Pearson, solicitor, chairman of the Bristol Corporation Electricity Committee, to report on the proposed electricity supply agreement.

Devonport.—The output from the electricity works for private lighting for the quarter ended September last shows an increase of 16,788 units over the corresponding quarter of last year.

Bristol.—It has been decided by the Electrical Committee to extend the alternating-current main to New Brislington. Short extensions of the main at Phippen-street, Malago Vale, and Queen-street have also been agreed to.

Tiverton.—The Town Council on Tuesday agreed to enter into a contract with Messrs. Suter and Co. for the construction of the electric light works, and to apply for sanction to borrow £12,200 for the undertaking.

Portsmouth.—A petition from inhabitants of Buckland and Kingston Ward, asking that arc lights should be substituted for what they called apologies of lamps in that district, has been referred to the Roads and Works Committee.

Lowestoft.—The electrical engineer's last report states that nine new consumers, representing 743 8-c.p. lamps, were connected up during last month, making a total of 442 consumers, representing 21,718 8-c.p. lamps now connected to the mains.

Coventry.—The Corporation propose spending £5,000 in purchasing additional motors to be let out on hire. They also contemplate the expenditure of over £31,000 in carrying out extensions in the electricity works to enable them to cope with the increased business.

Wandsworth.—The County of London and Brush Provincial Electric Lighting Company have informed the Borough Council that they would be in a position to deal with the question of a reduced charge for electric light when the figures for the current year were available.

Digitized by Google

Beverley.—The Corporation have instructed the town clerk to take the necessary steps for protecting the interests of the borough, after having received an intimation that the Lincolnshire and Yorkshire Electric Power Company intend to apply for powers to supply electricity in the borough.

Hamilton.—The Gilbert Arc Lamp Company, Limited of Chingford. have been asked to replace the existing street-lighting arc lamps in that town, as anticipated in our note on this subject on Nov. 27. The work has to be carried out very urgently, and is be completed in about four weeks.

Jarrow.—The Town Council have asked the County of Durham Electric Power Distribution Company if they will supply the electricity for the lighting of the town hall on a flat rate. We understand that this has been refused, and that the matter will be fully discussed at the next Council meeting.

Cheshire Electricity and Power Gas Bill.—At a meeting of the Cheshire Non-County Boroughs Association on Monday, the following resolution was unanimously passed: "That the various boroughs, members of this association, be advised to combine to offer the strongest opposition to the Bill at every stage."

Bangor.—The electrical engineer (Mr. Price White) in his report for the five weeks ended Nov. 28 states that, in comparison with the corresponding period last year, there had been an increase equivalent to 17·9 per cent. in the number of units of electricity sold. Up to Nov. 28 the works supplied current for 8,563 lamps of 8 c.p. each.

Erith.—The specification for the additional generating plant to be installed at the electricity works is divided up into five contracts—namely: (1) 7,500lb. Lancashire boilers, mechanical stokers for the boilers, pumps, and all accessories; (2) pipe work; (3) condenser; (4) steam alternator, with exciter; (5) extensions of main switchboard.

Swansea Telephones.—The Telephone Committee have decided to notify the National Telephone Company that it is the intention of the Council to demand intercommunication as from Jan. 1 next. It is further proposed to ask the company to appoint representatives to confer with the Council with reference to the methods of intercommunication.

King's Lynn.—The engineer's last report states that applications had been received for 114 additional lamps of 8 c.p., or equivalent, making a total of 17,067 from private consumers, and that five additional consumers had been entered, making a total of 440; 21,518 units had been sold during the month to private consumers, as compared with 14,938 for the same period last year.

East London and Lower Thames Power Bill.—The object of this Bill is to incorporate a company which shall establish generating stations and supply electric energy or power in the whole of the eastern and south-eastern districts, including Hackney, Bethnal Green, Stepney, Poplar, Deptford, Greenwich, Bermondsey, West Ham, and all the urban districts of South-East Essex.

Bridlington.—The Corporation's Bill was approved last week, and it was decided, on the recommendation of the Local Government Board, to alter the site of the proposed electric lighting generating station from the depôt in the hands of the Council to a site on the recently acquired Elms Estate, adjoining the main thoroughfare, between the old town and the new.

Bath.—On Nov. 25 it was reported to the Electric Lighting Committee that applications for new connections had been received equal to 481 8-c.p. lamps, and at a subsequent meeting on Dec. 4 this number was augmented by applications for connections amounting to 72 8-c.p. lamps. The maximum load occurred on Friday, Nov. 20, being 793·4 kw. as against 727 kw. for the corresponding week last year.

Dover.—At the last Council meeting attention was called to the inconvenience to business men caused by the breaking down of the telephone between Dover and Folkestone. For the last three days two miles of wire had been blown down. Considering the exposed nature of the coast, it was considered the wires should be underground, and the Council will make a representation to that effect to the National Telephone Company.

Camberwell.—It appears that the Borough Council have no objection to the proposed transference of the undertaking of the Crystal Palace District Electric Lighting Company to the Blackheath and Greenwich Electric Light Company, Limited, or the alteration of the system of supply, subject to the existing rights of the Borough Council to purchase the undertaking under the Crystal Palace District Lighting Orders not being prejudiced in any way by such transference or alteration of system of supply.

Gosport.—The Electricity Committee have informed the Board of Trade that the Provincial Tramway Company have entered into an agreement with the Council to put into operation the provisions of the lighting order. Steps are being taken to establish a power station and to lay the necessary mains for the purpose of supplying electric current for lighting purposes. Hope was expressed that the work would be finished in the winter of 1904.

Glasgow.—The Electricity Committee of the Town Council in their last report recommend that the extension of the generating station at Port Dundas be proceeded with, and that a deputation be sent to Sunderland and other English towns to see turbine machinery in connection with the proposed extension of the plant. Mr. Chamen, the engineer, reports that the contemplated extensions will cost £135,000, which would be distributed over a period of three years. Application is to be made to the Secretary for Scotland for sanction to borrow for capital purposes in conection with the department a sum of £250,000, being the balance of the half million authorised by the provisional order, 1901.

Wolverhampton.—At the last Town Council meeting, Councillor Allen referred to the comparative cost between lighting the streets with electricity and gas. He said the question was rather difficult to answer, because they had no record of the exact number of gas lamps that were replaced by arc lamps. Approximately there were 150 gas lamps replaced by 51 arc lamps. Now 150 gas lamps at £2. 18s. 1d. per lamp came to £435 per annum; 51 arc lamps at £22. 10s. per annum cost £1,150. As to candle-power, 150 gas lamps at 15 c.p. per lamp made a total cost of 2,250 c.p.; 51 arc lamps at 1,000 c.p. per lamp totalled 51,000 c.p. Cost per candle-power per annum: gas, 46·4d.; arc, 5·4d.

New Issue.—The Harwich Electric Lighting and Tramways Company, Limited, propose to acquire from the Harwich Corporation the right to supply electrical energy for public and private purposes. The Corporation are willing to make such a transfer of their privileges immediately the sanction of the Board of Trade can be obtained, and a suitable site has been already purchased for the erection of a generating station. The vendors to the company are the Electric Generating Stations, Limited, who have obtained the provisional order. The total share capital consists of £50,000, in shares of £1 each, and an issue of 25,000 shares, of which 3,000 are taken by the vendors, is just being offered for public subscription.

Islington.—At the last Borough Council meeting a letter was read from the London County Council Finance Committee drawing attention to the desirability of a sinking fund for the renewal and replacing of machinery being provided by those bodies who had taken up loans on electrical undertakings for a period of 42 years. The sum of £388,081 had been borrowed for that period, and up to March 31 last only £20,646 had been paid off those loans. Under those circumstances the Finance Committee regarded the creation of a reserve fund as desirable in the interests of finance, and invited the opinion of the Borough Council on the subject. The Council propose to borrow £849 for electric lighting purposes under those conditions.

Annual Dinner.—The electric lighting staff of the Sunderland Corporation held their fourth annual dinner in the Grand Hotel, Bridge-street, on Wednesday. Amongst the toast list we note: "The Mayor and Corporation," by Mr. E. White (station superintending engineer); "The Engineering Contractors and other Visitors," Mr. J. F. Moore; "The Borough Electrical Engineer and Staff of the Electrical Department," Alderman Bruce; "The Absent Members of the Staff," by Mr. J. J. Larkin. The musical programme was contributed to by Messrs. W. A. Thompson, E. Read, S. Lyne, Dan Noble, J. Bellamy, J. W. Wrightson, J. J. Larkin, L. G. Bain, F. W. Yeaden, R. D. Grieves, J. F. Moore; the piano accompaniments being played by Mr. J. W. Donkin and Master G. F. Dodds. The entertainment also included a recitation by Mr. G. A. Ferris.

Stock Exchange.—The Stock Exchange Committee has appointed special settling days as under: Dec. 23—Metropolitan District Railway Company's partly-paid scrip of a further issue of £500,000 4 per cent. perpetual debenture stock. Dec. 29—Dick, Kerr, and Co.'s 52,000 ordinary shares of £5 each, fully paid, Nos. 1 to 52,000; 61,000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 1 to 61,000; and £300,000 4½ per cent. debenture stock. The committee has also ordered the undermentioned securities to be quoted in the official list: British Columbia Electric Railway Company's further issue of 1,500 5 per cent. cumulative perpetual preference shares of £10 each, fully paid, Nos. 51,001 to 52,500; Dick, Kerr, and Co.'s 52,000 ordinary shares of £5 each, fully paid, Nos. 1 to 52,000; 61,000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 1 to 61,000; and £300,000 4½ per cent. debenture stock; and Metropolitan District Railway Company's partly-paid scrip of a further issue of £500,000 4 per cent. perpetual debenture stock.

Cardiff.—The National Telephone Company, Limited, have decided to greatly reconstruct the outside wires in Cardiff, and the question arises whether the present system of overhead construction is to be adhered to or whether the Council will give consent for underground work. The company's representative is to appear before the committee and present plans of what the company propose doing in the matter. The revenue of the electric lighting department for the current year was estimated at £27,000, but it is now believed that it will be £33,000. The electrical engineer, in his last report, states that there are now 948 consumers. The total number of units generated at the lighting station during the month was 177,291, and the estimated revenue was, from street-lighting, £456. 2s.; private supply, £2,728. 18s. 6d. The Mount Stuart Dry Docks, Limited, which takes its energy from the committee, wrote stating that they were very well pleased with the result of the year's working, and the manager (Mr. T. W. Wailes) said he could see nothing to prevent the company from being similarly successful in the future.

Camera Club.—At the Camera Club on Monday, Mr. R. W. Inward in the chair, Mr. T. C. Porter, M.A., F.I.C., etc., of Eton, in his well-known lucid manner, explained to an exceptionally large audience the phenomena of radium and the investigations of Röntgen, Crookes, Bequeral, Curie, Thompson, etc., which led to their discovery. He showed on the screen a slide taken from a plate which had been placed in contact with a small piece of ore containing 60 per cent. of thorium and the radiations emanating in right angles from each face were plainly discernible. That this mode of examining mineral ore may lead to great practical results will be clear to all "prospectors." An exceedingly interesting discussion followed, in which a number of medical men and others described some of their experiments and experiences. Mr. Martin Duncan also showed a few but very fine slides of Cornish pitchblends, and of a tube containing a 30 qr. of uranium nitrate at various degrees of heat, which showed that its radiations make a good impression on the plate up to 130deg. C., but degenerates when the mineral is heated to a higher temperature. The fixtures for January include papers on the dust-raising qualities of motorcars, by Colonel Crompton, C.B., and Mr. Crawley, and a demonstration by Dr. George Redman concerning the photography of some electrical phenomena.

Digitized by Google

Street.—The Urban District Council will not share in the guarantee as proposed at the recent meeting of the Joint Committee from the Councils of Wells, Shepton Mallet, Glastonbury, and Street, appointed to confer as to the acquisition of the telephone. It was proposed that the basis of contribution to the guarantee fund should be according to population, but if 60 subscribers could be obtained from the whole district (at a minimum subscription of £4 each) there would be no financial liability.

Lytham and St. Annes.—Application is to be made to the Local Government Board for sanction to borrow £4,000 for the extension of electricity mains and services. The electrical engineer in his last report states that satisfactory progress had been made during the past month, the output continuing to increase. The number of applications for supply was over the average. There were 46,826 units sold, as compared with 14,829 in the corresponding period last year, and the total number of units sold so far this year reached 254,208, as against 64,823.

Battersea.—The Council propose to undertake to instal the electric light in the clock tower of St. Peter's Church at an estimated cost of £56, and to maintain the installation at an estimated annual charge of £34 under the provisions of the Act in question. The Wandsworth Borough Council is to be asked to reconsider the application of the Council to light by electricity, at an annual cost of £16 per lamp per annum, the eastern portion of Nightingale-lane maintained by them under the provisions of the order of the London County Council dated July 30, 1901.

London County Council.—On Tuesday it was agreed to lend the St. Pancras Borough Council £5,764 for street-lighting purposes. The Main Drainage Committee made the following report: "On Nov. 3 last the Council referred to us several tenders for the supply and erection of electrical machinery and fittings at the Abbey Mills pumping station. Upon further consideration of the matter, however, we are of opinion that the work of providing an electric light installation at this station should be postponed for some time, and we do not therefore propose to report on the tenders at present."

Swinton.—At a meeting of the Swinton and Pendlebury District Council on Monday, the Tramways and Electricity Committee reported that instructions had been given to the clerk to communicate with the Salford Corporation and the Lancashire Tramways Company to ascertain the most favourable terms upon which a supply of electricity in bulk could be obtained by the Council. On the question of the electric supply of the district a deputation from the Swinton and Pendlebury Ratepayers' Association had a private interview with the Council at the close of the ordinary business.

Dundee.—Arrangements are being made for beginning next week the laying of the new electric mains in the centre of the city. The Council some time ago sanctioned an expenditure of £9,000 for this work, which involves the relaying of the whole of the cables. It is expected, however, that it will be possible to carry out the work without interfering in any way with the supply of current. The station is now in a position to supply any demands that may be made on it for power or for lighting purposes. With regard to the proposed power scheme recently noted by us it is reported that the total £200,000 required has been subscribed.

Pemberton.—The total current generated during October was 32,754 units, and the total sold 24,873 units, a percentage of 76. Mr. Heaton estimates that the construction of a new shaft at Nicholson's pit will cost about £350. Tenders for the work are to be advertised. Last week saw the inauguration of two new engines of 500 h.p. each, which it is hoped will have much work in the near future in the supply of electricity for motor purposes, and particularly in the development of the new system of tramways. The engines have been built by Dick, Kerr, and Co., Limited, of Preston, and have been placed alongside the first two put down by the same firm.

Watford.—In connection with the proposal referred to by us last week—viz., that an application be made to the North Metropolitan Electric Supply Company to ascertain whether they would be prepared, and if so on what terms, to acquire the electric lighting undertaking of the Watford Urban District Council, and to supply the district of the Council with electrical energy—a public meeting has been called to discuss a resolution to the effect that the ownership and control of the electric light should be retained by the town, and protesting against the Urban District Council taking any steps to dispose of the undertaking without first obtaining the sanction of a substantial majority of its constituents.

Yarmouth.—The Council have decided to spend £240 for a supply of additional transformers for the purpose of improving the lighting throughout the system. The Electric Lighting Committee have been considering the question of carrying an electric cable across the harbour. It appears from correspondence that the Port and Haven Commissioners require the trench for the cable to be 21ft. below low water. This requirement the committee did not consider reasonable, and suggested 19ft., but preferred to have the cable carried over the river by means of steel masts, or by attachment to a transporter bridge at a minimum height of 130ft. The Commissioners will now be asked for their concurrence to either method.

Belfast.—The Gas and Electric Committee have passed the following resolution: "That, in order to meet the wishes of those consumers of electric current who are of opinion that the charges made for current are excessive, the Council be recommended to apply to the Board of Trade to appoint an inspector for three months for the purpose set forth in Section 27 of the Electric Lighting Orders Confirmation Act (No. 7), 1890, as the committee is of opinion that it would be for the benefit of the undertaking, and in the interests of the public, that this step should be taken." The resolution will come before the Corporation at the meeting on Jan. 1 next. Mr. M'Cowen has obtained permission to make a short extension along the Lisburn-road, and also in Ormeau-avenue. The work will cost close on £875.

Beckenham.—The Urban District Council have adopted a report recommending the Council to exercise the power conferred upon them by Section 70 of the Crystal Palace and District Electric Lighting Order, 1890, and require the company to sell to the Council, on the terms set out in the said order, so much of their undertaking as is situated within Beckenham parish. The report further stated that tenders for free wiring had been referred to the engineers, with instructions to communicate with three of the persons tendering and arrange for the approval of the committee a uniform schedule of prices for wiring and fittings, with a view to contracts being entered into. The officers are to report in writing on the financial position of the free wiring scheme and on the proposal to wire houses during construction. A cable is to be laid in Tudor-road at an estimated cost of £60.

Paignton.—A deed of agreement has been drawn up between the National Electric Construction Company and the Council as to lighting the town, and Messrs. Enright have been provisionally appointed consulting engineers. At a meeting of the ratepayers' association on Friday it was proposed that, having regard to the financial position of the Council, to the large and uncertain expenditure upon waterworks beyond the £70,000 already sanctioned, and also to the pressing need of carrying out an expensive drainage scheme, for which plans were prepared in 1895, this meeting is of opinion that the proposed electric lighting scheme, which will impose an additional burden upon the rates without any prospect of being remunerative, ought not to be entertained. A voluntary postcard poll was suggested, but the meeting broke up late and somewhat hastily without coming to any decision.

Clydebank.—At the meeting of the Town Council on Tuesday the agreement with the Clyde Valley Electrical Power Company on the question of taking over the powers obtained by the burgh under the electric lighting provisional order was confirmed. The company agree to pay the Council in full reimbursement of the cost of the order the sum of £400, and in consideration of its transfer £100 per annum for a period of 10 years. At the end thereof such annual payment shall be subject to a reduction of £2 per annum for each arc lamp, or for every 10 incandescent lamps or their equivalent. The company agree to supply electric energy and voltage for public lighting, the Council paying £10 per annum for each arc lamp used by them for street-lighting, and £1. 2s. for each 16 c.p. incandescent lamp. The Council have power in the agreement to resume possession of the power under the order at certain periods under certain conditions.

Brixham.—At the meeting of the District Council on Monday a deputation presented a memorial, which stated that at a meeting on Saturday night it had been resolved to inform the Council that in the opinion of the ratepayers and a large number of others there would be no demand for electricity outside the Council sufficient to make the scheme a remunerative one; also, that there should be a clear majority in favour of the scheme; that it had been found by experience that crooked and narrow streets like Brixham's were unsuitable to electric lighting; that it was unwise to lay a further debt on the town, as the finances were limited until the water scheme and the widening of Fore-street had been carried out. The Council did not come to any decision, and everything was left in abeyance. The Clerk suggested that formal notice of objection should be made to the Bill, and it was decided to wait until they could learn how the inhabitants had responded to the notices served on them.

Marine Steam-Turbine.—We are informed that the American Westinghouse Company have acquired the full rights to manufacture the Parsons steam-turbine in the United States and Canada for all purposes, including that of marine propulsion. A special department is being organised at Pittsburg for building this type of engine for vessels of every class, including warships; and this work will be carried on in close touch with the shipbuilders all over the country. There are some half million horse-power of Parsons steam-turbines in daily operation in different parts of the world, 84,000 h.p. being used for steamships' propulsion. In the United States alone some 60,000 h.p. of turbine engines are employed in electricity generation, and 150,000 h.p. more are under construction. Engines as large as 8,000 h.p. are already being built at Pittsburg, and the Westinghouse Company look forward to immense developments in this new branch of industry, more especially with regard to ship work.

Tamworth.—At Saturday's meeting of the Rural District Council a notice was considered of the intention of the Tamworth Corporation to apply to the Board of Trade for a provisional order authorising the supply of electrical energy within certain parts of the rural district, and application for the Rural District Council's consent to the granting of such provisional order, and the waiver of the notice required by the Electric Lighting Act, 1882, to be given by the Council. A resolution of the Bolehall and Glascote Parish Council was read in opposition to the granting of the order. It was proposed that the Council assent to the waiver of notice, and it was pointed out that they did not want to upset the Corporation. In the meantime a committee might consider whether they should oppose the scheme wholly or in part. The reason Bolehall and Glascote Parish Council decided to oppose those powers was because at present they had no proof that the Tamworth Town Council would supply them with electric power and light. As soon as they got an undertaking from the Corporation that they would supply them in a reasonable time they would withdraw their opposition. It was agreed not to take any action whatever that day.

Bootle.—The proceedings of the Electric Power and Lighting Committee with reference to extensions of distributing mains in certain streets were approved at the last Council meeting. The Chairman referred to the fact that all the applications for the supply of electricity had been successfully attended to, and said he had to congratulate the Council on the success of the electricity undertaking. About this time last year they had 3,000 units working, and now they had the whole 5,000. They had not moved too soon in the election

Digitized by Google

of their new works. Only for the prevention of the weather and other circumstances over which they had no control, they would have been a still greater success. He called the attention of the Council to the notice of motion, as under, and said he was in a position to give a perfect answer to the questions he was about to ask. The motion read as follows: "That the Electric Power and Lighting Committee be directed to report to the next meeting of the Council with reference to the following points in connection with the contract of Messrs. Ferranti Limited with the Corporation for the supply of electrical machinery—namely: (1) the power of the engines contracted to be supplied; (2) the power of the engines actually supplied; (3) what deviations have been made from the terms of the contract, and the necessity for such deviations." After discussion it was agreed that an electrical engineer of repute be employed to report upon the machinery they had already received, and that a sub-committee, composed of the mayor, chairman, and deputy-chairman of the Finance Committee, should take the matter into consideration.

Colchester.—At the invitation of the firm of Messrs. Davey, Paxman, and Co., a large gathering, including the Mayor and Mayoress (Councillor and Mrs. E. H. Barritt), most of the members of the Corporation, and numerous other prominent townspeople, assembled on Friday afternoon at the Colchester electric light station to witness the starting by the Mayoress of a large new 550-h.p. engine, which has recently been fixed by the firm. The Mayor gave some statistics of the growth of the electrical undertaking since its inauguration five years ago, and said that it began with a maximum of 4,500 lamps, and the plant was of 180 kw. capacity, with three dynamos and three engines of 100 h.p. each. At the end of a year 4,250 lamps were connected, and at the end of 18 months the increasing applications for current led to the instalment of a fourth engine of 220 kw., bringing the capacity up to 400 kw. and the horse-power to 660. During the second year the number of lamps connected increased to 9,350, and in November, 1901, when the pressure was doubled, the number was 13,000. In order to cope with the demand, another 260-h.p. engine, with an output of 175 kw., was installed, which had met the requirements up to the present, but it became necessary early this year to make further provision, the number of lamps connected having risen to 20,000. To-day they had 25,000, and if all the lamps were lit simultaneously, they would, without the new engine, have been unable to supply current for over 1,000. The new engine, of 550 h.p. and 375 kw. capacity, made them able once more to meet all the demands that might be made, and those demands were yet fast coming in. Mr. A. R. Sillar, the electrical engineer, said he believed the engine would prove even more satisfactory than the old engines, which had never yet broken down.

London Gazette.—Mr. Richard Davis Willis has been released from trusteeship in the estate of Lewis Bayliss (carrying on business as F. Terrill and Co., and as Cordwell and Co., also as Thames Electrical Manufacturing Company), electrical accessories manufacturers, residing at Ridding-lane, and carrying on business at Brunswick Park, Wednesbury, and at 110, Cannon-street, London, E.C., and at 1 and 2, Bucklersbury, London. Mr. William Arthur Turner has been appointed trustee in the estate of Cecil Wray, mechanical and electrical engineer, 16, Chevin-view, Eccleshill, formerly of 24, Simes-street, Bradford. The first meeting in the estate of Thomas Hyam, gas and electric light fitter and plumber, 139, Fawcett-road, Southsea, Hants, will be held on Dec. 23, at 3 p.m., at the Official Receiver's Office, Cambridge Junction, High-street, Portsmouth. At a general meeting of the shareholders of the British Electric Car Company, Limited, held at the company's works, Trafford Park, Manchester, on Dec. 7, the resolution was passed that it had been proved that the company could not continue its business, and that the company should be wound up voluntarily. Mr. Thomas Frederick Wild, chartered accountant, of 23, Broad-street-avenue, London, E., was appointed liquidator. At a general meeting of the British Schuckert Electric Company, held on Nov. 17, it was decided that the company be wound up voluntarily, and that Mr. Arthur Jacob, the general manager of the company, be liquidator. A general meeting of members of Imperial Electric Supplies, Limited, will be held at 5, Gray's-inn-square, London, on Jan. 15, 1904, at 12 o'clock noon, to have an account laid before them showing the manner in which the winding-up has been conducted and the property of the company disposed of, and of hearing any explanation that may be given by the liquidator. The partnership subsisting between Wolfram Court and Henry Taylor, electrical and motor engineers and contractors, 53, Broadway, Wimbledon, S.W., trading as Court and Taylor, has been dissolved from Nov. 14, 1903. All debts due and owing will be received and paid by Wolfram Court, who will continue the business. The partnership subsisting between Stephen Appleyard and Thomas Stather, electrical engineers, 25 and 26, Hopwood-street, Hull, trading as Appleyard and Stather, has been dissolved from Nov. 16. The partnership subsisting between Cecil Douglas Falcke and Percival West, electrical fittings manufacturers, 113, Coleshill-street, Birmingham, trading as the Birmingham Electrical Fittings Company, has been dissolved.

Brighton Telephones.—The Council have received from the Postmaster-General a letter containing the following paragraph: "As regards the offer of a free service until the number of subscribers to the Corporation system throughout the area reaches 750, which is stated by the Mayor to have been made generally throughout the area, I am to say that the Postmaster-General is advised that the Corporation are not entitled under their license to give an exchange service without charging subscribers at some rates within the specified limits. In the establishment of other corporation systems it has been recognised that some interval must elapse between the connection of the first subscriber and the opening of the exchange service for which subscribers pay subscriptions, and during this interval no question has been raised as to the moderate experimental use which has been made of the comparatively small number of lines connected with the exchange. It would appear, however, that the Corporation of Brighton intend to go beyond the limits which have been observed by other corporations, and to offer to subscribers, and especially to subscribers who at present have lines provided by the National Telephone Company, an effective exchange service without payment. The Postmaster-General regards such an arrangement as a breach of Clause 11 of the Corporation license, and I am to ask that subscriptions at rates within the specified limits may at once be collected from all subscribers who are enjoying an effective exchange service. The Postmaster-General notes the Mayor's assurance that the offers of money which have been made to subscribers of the Telephone Company at Burgess Hill have been made by the chairman of the Telephone Committee without the knowledge of the Corporation, and that there is no possibility of any disbursements in this respect being repaid to him by the Corporation. Lord Stanley cannot, however, dissociate the Corporation from responsibility for the acts of the chairman of their committee, and as those acts constitute a breach of the conditions contained in Clause 21 (1) of the Corporation license, which forbids the giving of favour or preference, he considers that the offers made to the Telephone Company's subscribers at Burgess Hill should be at once withdrawn." In their reply the Telephone Committee at once agreed to the request contained in the latter lines, and with regard to the former issue say that they regret to learn the opinion which the Postmaster-General has expressed with respect to the course the Corporation are taking with a view to establishing an effective exchange before charging rents for the services now being connected with the Corporation system of telephones, and which opinion appears to the committee to be based in a large measure on inaccurate and incomplete information. In the first place, the committee assure the Postmaster-General that the representation made to him that an offer has been made by the Corporation "to subscribers who at present have lines provided by the National Telephone Company" other than that made to all subscribers to the Corporation system, is contrary to the fact. The promise which has been made to subscribers of the National Company is exactly the same as that made to all other subscribers—namely, that no charge will be made until 750 subscribers are attached to the system— in other words, until there is what will, in the opinion of the Corporation, be an effective exchange service. The committee are informed that in adopting this course they are following the usual practice in telephone business in all countries in the world as well as that of the National Telephone Company, and they are of opinion that it is not possible to establish an exchange in any other way, as it is certain no person would pay for a telephone until he had a sufficient number of others to talk to to render the instrument useful The committee are officially informed that in Glasgow no charge was made to subscribers until after a lapse of five months after the switching-on began, and that at the date when rates were first charged the number of subscribers working was 1,450, and that at Portsmouth no charge was made until 700 had been connected. In the case of Swansea, where the Corporation system only provided for 750 lines, the number of subscribers at the date of the formal opening was 366, or nearly half the total. The Brighton Corporation are providing for an exchange of 2,000 lines, the first of which was connected on Oct. 5 last, and the committee submit that, having regard to the total number of lines being provided, 750 is not an unreasonable number to constitute an effective exchange for the borough and the other towns and parishes within the Brighton telephone area, and that in fixing that number the Corporation of Brighton are not going beyond the limits observed by other corporations. The present number of subscribers connected with the exchange is 284, nearly all of whom are situate in a very limited area closely approximate to the exchange.

PROVISIONAL PATENTS, 1903.

DEC. 7.

26687. Improvements in electric lamps for motorcars and vehicles. Robert Lee, 203, Shaftesbury-avenue, London.

26772. Improved arc lamp for high tensions. Tito Livio Carbone, 322, High Holborn, London. (Complete specification.)

26773. Improved arc lamp with convergent downwardly directed carbons. Tito Livio Carbone, 322, High Holborn, London. (Complete specification.)

26776 Improved manufacture of incandescence bodies for electric glow lamps. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Actien Gesellschaft, Germany.) (Complete specification.)

26783. Improvements in electrically operated railway switches. Claude Webster Breedlove and Rudolph Redell Grant, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26788. Improvements in electromotors of the induction type. Frank Michael Lewis, Norfolk House, Norfolk-street, Strand, London.

26792. Improvements in electric sanitary closets. James Horace Wilson, 18, Buckingham-street, Strand, London. (Complete specification.)

DEC. 8.

26808. Improvement relating to telegraph poles and the like. Wilfred Lawson Bullows, Long-street Works, Walsall.

26823. Improvements in lighting by electricity, gas, and other illuminants public throughfares, streets, and places, and appliances therefor. James Townsley Pearson, 8, St. James's Hall, Burnley.

Digitized by Google

26825. Improved electrical device to indicate when trolley leaves the wire. George Edwin Watmough, 6, Hill Top-avenue, Roundhay-road, Leeds.

26827. Improved wind motors for the generation of electricity and for other purposes. David Burns and James Macarthur Fleming, 37, West-Nile-street, Glasgow.

26842. Improvements in electric automatic cut-outs or switches. Crompton and Co., Limited, and Arthur John Hodgson, The Arc Works, Chelmsford.

26843. Improvements in arc lamp suspension apparatus. Crompton and Co., Limited, and Arthur John Hodgson, the Arc Works, Chelmsford.

26848. Telephone systems. Wallace Fairweather, 65, Chancery-lane, London. (The Stromberg Carlson Telephone Manufacturing Company, United States.) (Complete specification.)

26849. Telephone systems. Wallace Fairweather, 65, Chancery-lane, London. (The Stromberg Carlson Telephone Manufacturing Company, United States.) (Complete specification.)

26850. Selective signalling systems. Wallace Fairweather, 65, Chancery-lane, London. (The Stromberg Carlson Telephone Manufacturing Company, United States.) (Complete specification.)

26851. Improved central exchange apparatus and connection. Wallace Fairweather, 65, Chancery-lane, London. (The Stromberg Carlson Telephone Manufacturing Company, United States.) (Complete specification.)

26856. Improvements in and relating to electric circuit-breaker mechanism. Crompton and Co., Limited, and Robert Charles Harris, 55, Chancery-lane, London.

26857. Improvements in electric arc lamps. Crompton and Co., Limited, and Arthur John Hodgson, 55, Chancery-lane, London.

26862. Instrument for determining the deviation of magnetic compasses from the true meridian. Adolph Lietz, 52, Chancery-lane, London.

26863. Telephonic recorder. Stanley Rowe, 12, Franconia-road, Clapham, London.

26873. Improvements in automatic telegraph apparatus. George Lewis Hogan, 27, Chancery-lane, London.

DEC. 9.

26912. Improvements in or connected with incandescent electric lamps. George Davis, 15, Victoria-street, London.

26913. Telephone exchange system. James Swinburne and Granville Hugh Baillie, 82, Victoria-street, London.

26915. Improvements in connection with wall sockets and switches for electric circuits. George Edwin Fletcher, 17, St. Ann's-square, Manchester.

26916. Improvements in means for advertising on electric tramcars and other electric vehicles. Albert Edward Walkden, 17, St. Ann's-square, Manchester.

26922. Improvements in connection with the laying of electric cables and the like. William Michael Rogerson, Commercial-street, Halifax.

26935. An electrical controller. David E. Evans, The Court, Pencoed, South Wales.

26947. Improvements in automatic electric street indicators for cars. Frank Henry Wehrmann, 605, Missouri Trust-building, St. Louis, Missouri, U.S.A. (Complete specification.)

26954. A mechanical device applied to the cars or cages of electrically-driven lifts and belt-driven lifts. Alexander Charles Moffatt, 67, Knatchbull-road, Camberwell, London.

26961. Improvements in switching mechanism for double-filament electric lamps. John McCullough, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 10, 1902, being date of application in United States.) (Complete specification.)

26963. Improvement in relation to the suspension of magnetic compasses and other instruments. George Charles Lilley, Billiter House, Billiter-street, London.

26965. An improved clutch for electric arc lamps. Henry Bevan Swift, 31, Waldegrave-road, Upper Norwood, London.

26967. Electric switch. Axel Theodor Wedelin, 18, Eldon-street, London.

DEC. 10.

27032. Improvements in dynamo-electric machines. Henry Chitty, 2, Norfolk-street, Strand, London.

27038. Improvements in sand valve, gear, and tramp for use on electric cars. Henry Liddle, 132, Ethel-street, Benwell, Newcastle-on-Tyne.

27079. Improvements in the construction of induction coils for medical and other purposes. Charles Chalmers Fontaine, 37, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 31, 1903.

1902.

27618. Devices for varying the resistance of an electric circuit. Siemens Bros. and Co., Limited, and Siemens.

27676. Form of hydraulic press for assembling the parts of electrical commutators, tightening the ends of electrical commutators, and pressing together the discs of electrical armatures. Petch.

1903.

1067. Electrical measuring instruments. Carolan. (General Electric Company.)

2695. Insulating materials and artificial substitutes for ebonite and the like. Lucas.

2879. Electrically-operated clocks. Loebl, Scott, and American Electrical Novelty and Manufacturing Company, Limited.

2963. Telegraph and telephone cables and the like. Mansbridge.

15481. Electric arc lamps. Viale.

21404. Electricity meter for alternating currents. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellschaft.)

21760. Electrical measuring instruments. Beez.

22365. Electromagnets. Baxter. (Date applied for under International Convention, Nov. 21, 1902.)

23057. Single-phase alternating-current motors. Lamme. (Date applied for under International Convention, Oct. 31, 1902.)

24127. Electric bath tubs and electrodes therefor. Zwiebel.

24212. Means for controlling arc lamps. Haddan. (Zielenziger.)

24302. Magneto-electric induction apparatus. Bloxam. (Schoeller.)

24396. Galvanic batteries. Risac.

EXPERIMENTS ON EDDY CURRENTS.*

BY W. M. THORNTON, D.SC., MEMBER.

§ 1. Experiments on Massive Cast-Iron and Steel Rings.

Eddy currents are induced in solid masses of metal by any variation of a magnetic field traversing them. The loss of efficiency of dynamo-electric machines from this cause can be approximately determined from the fact that while other losses caused by hysteresis, mechanical friction, and windage vary directly with speed, eddy-current losses are proportional to its square. The usual way of conducting the separation test is to run the machine light, at the same excitation but at different speeds, as a separately excited motor, and to plot the current taken by the armature vertically, the brush voltage or speed horizontally. A line is obtained which cuts the vertical axis, and the current required to overcome the eddy-current loss is the height of the line above a horizontal through this point of intersection. Measured in this way eddy loss is found to account for 25 to 50 per cent. of the loss of efficiency at light load. (Hawkins and Wallis: "The Dynamo," third edition, p. 689.) The increased loss at full load depends very much on the construction of the machine. It is greater with poles and pole-faces of high electrical conductivity than with cast iron, because the circulation of the local eddies varies not only inversely with the specific resistance, but as the square of the permeability. It is for this reason that they are much greater in iron than in copper, for the ratio μ^2/ρ is 500,000 times greater for the former than the latter at ordinary flux densities. A comparatively small variation of magnetisation will therefore give rise to strong currents when they are permitted to flow.

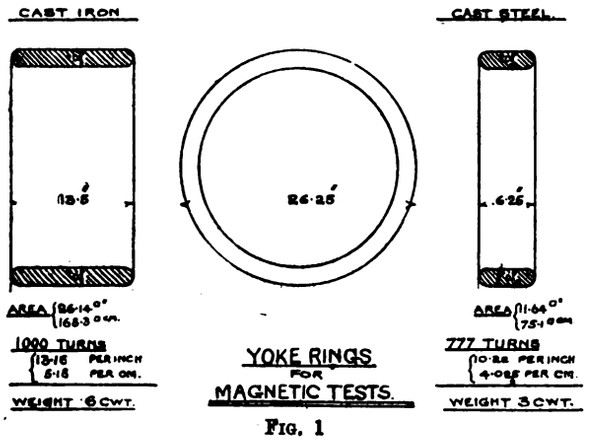

Fig. 1

Before examining in detail the losses in a machine, it is well to know how eddy-current loss is related to hysteresis and copper losses in the most perfect case—that is, of a massive closed iron ring covered with a uniform winding and excited by an alternating current. For this purpose it is only necessary to measure the current taken and watts absorbed by the coil under different conditions of excitation and at different frequencies. Tests were made on two yoke rings (Fig. 1), kindly lent by Messrs. W. H. Allen and Co., the hysteresis loops of which have been determined by a special method independent of the influence of eddy currents in the core. Each ring was connected in turn first to the supply mains at a frequency of 83, and then to experimental alternators giving either 18 or 37 periods per second. The results are recorded in Table I.

When the frequency is high it is impossible to work out the hysteresis loss from loops obtained by a slow cyclic process, but when the magnetisation is less than saturation the eddy-current and hysteresis losses can be separated by considering the latter to be proportional to the rate of change of the induction—that is, for low values to the exciting current—and the former to its square. Thus, if w represents the total watts less the copper loss it can be written

$$w = a\,i + b\,i^2,$$

where a is the watts lost by hysteresis per ampere and b those lost by eddy currents per (ampere)^2. a and b can be found from two readings:

$$w_1 = a\,i_1 + b\,i_1^2,$$

$$w_2 = a\,i_2 + b\,i_2^2;$$

so that

$$a = \frac{w_2\,i_1^2 - w_1\,i_2^2}{i_1\,i_2\,(i_1 - i_2)},$$

and

$$b = \frac{w_1\,i_2 - w_2\,i_1}{i_1\,i_2\,(i_1 - i_2)}.$$

* Paper read before the Newcastle Local Section of the Institution of Electrical Engineers, Dec. 14.

Table I.—Cast-Steel Ring.

Volts.	Amperes.	Watts.	cos φ	) (	$r i^2$	Hysteresis watts.	Eddy watts.	Eddy / hysteresis.	V / A ohms.

89·	6·25	502	·9	18·8	20·2	20·2	407·3	20·3	14·2
Cast-Iron Ring.									
100	·67	60·5	·9	83·5	1·3	21	38	1·8	149
37	·39	13	·9	37	·44	8·6	4·3	·5	95
45·2	·534	21·4	·89	37	·83	12·5	8·0	·64	85
102·5	·782	68·4	·84	37	1·78	49·6	17	·34	132

At the higher frequency the greatest value of b for the steel ring is *25* watts per (ampere)^2, and of a 31·6 watts per ampere, but these coefficients vary with the saturation, and should be determined from adjacent values for the whole range of excitation. Thus, for the lowest current b is *12·25*. In this way the eddy-current and hysteresis losses have been calculated. At the lower frequency it has been assumed that the shielding effect is not sufficient to lower the magnetisation reached at the inner parts of the core, because the long thin cross-section is very much less favourable to the flow of eddy currents than a circular area. The values of the hysteresis watts have in these cases first been found from the loops and the eddy loss deduced, but the results were also checked by the above method with an agreement within a few per cent. For example, the calculated values in Column 8 corresponding to 241·3 and 407·3 are respectively 240 and 402.

Much difficulty was experienced with the cast-iron ring in getting consistent readings. This was found to be due to the retentiveness of the iron. The highest alternating voltage available in the laboratory is 100, and not having a suitable transformer the greatest current reached at the highest frequencies was ·67 ampere. The power factor was found by the oscillograph and the watts calculated, but there is little practical interest in these very low magnetisations. Typical oscillograms are given in Curves I. and II. (Fig. 2). By an inspection of the tables and Fig. 3 it will be seen that as losses increase the power factor decreases. This cannot be due to the increase in permeability, for that is higher at the lower magnetisations. It means that with small coil currents, the eddies are sufficiently great on account of the high values of μ to prevent waves of any strength entering the core. When the whole core is magnetised by the large coil currents, the loss by eddy currents is increased, not because of their greater intensity, but of the larger area of the core brought into activity.

It is interesting to compare the behaviour of the two rings. The area of the iron ring is 2·25 times that of the steel. Its permeability is about one-half; the ratio of the turns on the windings are as 1·285 to 1. The inductance of a coil with a laminated core being

$$L = 4\,\pi\,T^2\,A\,\mu/l,$$

where T is the total turns, A the cross-sectional area of the core, μ its permeability, and l its mean length, the corresponding inductance of the iron ring is 2·84 henries, which is 1·44 times that of the steel. The resistance of the "iron" coil is 2·9 ohms, that of the steel 1·9. These are too low to affec t the impedance, and the inductance would with laminated cores be in the ratio 1·44 to 1. They are actually 5 to 1.

Table II.

—	Cast iron.	Cast steel.
Mean permeability from loops	$\mu_1 = 360$	*520*
Calculated inductance	2·84	1·98
Observed impedance	149	30·58
Resistances of windings	2·9	1·9
Frequency	83·5	83·5
Observed inductance	·445	·058
Actual permeability of cores as a whole	$\mu_2 = 40$	*19·8*
Ratio μ_1/μ_2	6·5	26·3
Frequency	37	13·3
Observed impedance	132	18·1
Observed inductance	·57	·034
μ_2	51·5	11·7
Ratio μ_1/μ_2	5·05	44·5
